Introduction 1

2016.10.28

NII51001

This handbook describes the Classic processor from a high-level conceptual description to the low-level details of implementation. The chapters in this handbook describe the Nios II processor architecture, the programming model, and the instruction set.

This handbook describes the processor from a high-level conceptual description to the low-level details of implementation. The chapters in this handbook describe the processor architecture, the programming model, and the instruction set. The processor is only availabe in the 14.1 release and above.

We have ended development of new Classic processor features with the 14.0 release. New features are implemented only in the processor core. Although the Classic processor remains supported, we recommend that you use the core for future designs.

This handbook assumes you have a basic familiarity with embedded processor concepts. You do not need to be familiar with any specific FPGA technology or with FPGA development tools. This handbook limits discussion of hardware implementation details of the processor system. The processors are designed for FPGA devices, and so this handbook does describe some FPGA implementation concepts. Your familiarity with FPGA technology provides a deeper understanding of the engineering trade-offs related to the design and implementation of the processor.

This chapter introduces the FPGA Nios II embedded processor family and describes the similarities and differences between the processor and traditional embedded processors.

Processor System Basics

The processor is a general-purpose RISC processor core with the following features:

- Full 32-bit instruction set, data path, and address space
- 32 general-purpose registers
- Optional shadow register sets
- 32 interrupt sources
- External interrupt controller interface for more interrupt sources
- Single-instruction 32 × 32 multiply and divide producing a 32-bit result
- Dedicated instructions for computing 64-bit and 128-bit products of multiplication
- Optional floating-point instructions for single-precision floating-point operations
- Single-instruction barrel shifter

- Access to a variety of on-chip peripherals, and interfaces to off-chip memories and peripherals
- Hardware-assisted debug module enabling processor start, stop, step, and trace under control of the Nios II software development tools
- Optional memory management unit (MMU) to support operating systems that require MMUs
- Optional memory protection unit (MPU)
- Software development environment based on the GNU C/C++ tool chain and the Nios II Software Build Tools (SBT) for Eclipse
- Integration with FPGA's Signal Tap* Embedded Logic Analyzer, enabling real-time analysis of instructions and data along with other signals in the FPGA design
- Instruction set architecture (ISA) compatible across all processor systems
- Performance up to 250 DMIPS
- Optional error correcting code (ECC) support for a subset of processor internal RAM blocks

A processor system is equivalent to a microcontroller or "computer on a chip" that includes a processor and a combination of peripherals and memory on a single chip. A processor system consists of a processor core, a set of on-chip peripherals, on-chip memory, and interfaces to off-chip memory, all implemented on a single FPGA device. Like a microcontroller family, all processor systems use a consistent instruction set and programming model.

A processor system is equivalent to a microcontroller or "computer on a chip" that includes a processor and a combination of peripherals and memory on a single chip. A processor system consists of a processor core, a set of on-chip peripherals, on-chip memory, and interfaces to off-chip memory, all implemented on a single FPGA device. Like a microcontroller family, all processor systems use a consistent instruction set and programming model.

Getting Started with the Nios II Processor

The easiest way to start designing effectively is to use an development kit that includes a ready-made development board and the Nios II Embedded Design Suite (EDS) containing all the software development tools necessary to write Nios II software.

The Nios II EDS includes the following two closely-related software development tool flows:

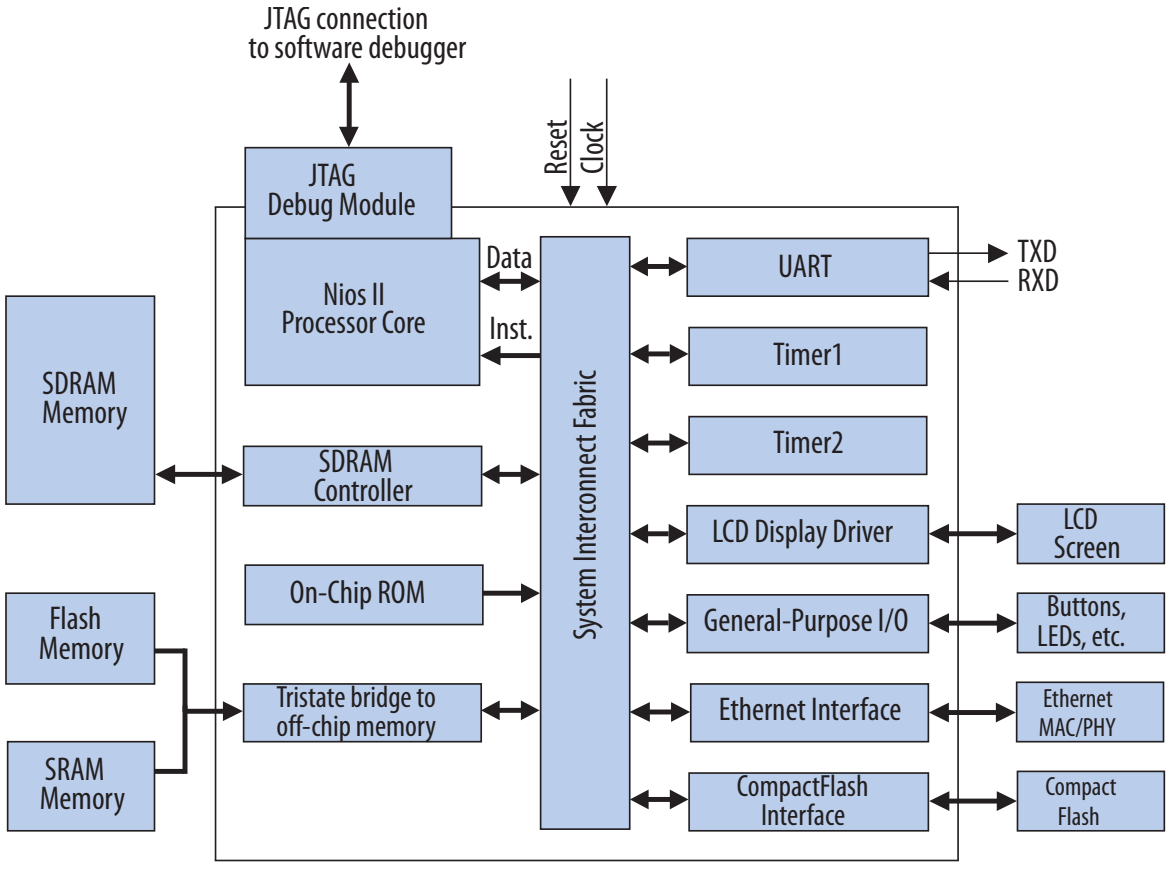
- The Nios II SBT
- The Nios II SBT for Eclipse

Both tools flows are based on the GNU C/C++ compiler. The Nios II SBT for Eclipse™ provides a familiar and established environment for software development. Using the Nios II SBT for Eclipse, you can immediately begin developing and simulating Nios II software applications.

The Nios II SBT also provides a command line interface.

Using the hardware reference designs included in an development kit, you can prototype an application running on a board before building a custom hardware platform.

Figure 1-1: Example of a Processor System



If the prototype system adequately meets design requirements using an -provided reference design, you can copy the reference design and use it without modification in the final hardware platform. Otherwise, you can customize the processor system until it meets cost or performance requirements.

Customizing Processor Designs

In practice, most FPGA designs implement some extra logic in addition to the processor system. FPGAs provide flexibility to add features and enhance performance of the processor system. You can also eliminate unnecessary processor features and peripherals to fit the design in a smaller, lower-cost device.

Because the pins and logic resources in FPGA devices are programmable, many customizations are possible:

- You can rearrange the pins on the chip to simplify the board design. For example, you can move address and data pins for external SDRAM memory to any side of the chip to shorten board traces.
- You can use extra pins and logic resources on the chip for functions unrelated to the processor. Extra resources can provide a few extra gates and registers as glue logic for the board design; or extra resources can implement entire systems. For example, a processor system consumes only 5% of a large FPGA, leaving the rest of the chip's resources available to implement other functions.
- You can use extra pins and logic on the chip to implement additional peripherals for the processor system. FPGA offers a library of peripherals that easily connect to processor systems.

Configurable Soft Processor Core Concepts

This section introduces Nios II concepts that are unique or different from other discrete microcontrollers. The concepts described in this section provide a foundation for understanding the rest of the features discussed in this handbook.

Configurable Soft Processor Core

The processor is a configurable soft IP core, as opposed to a fixed, off-the-shelf microcontroller. You can add or remove features on a system-by-system basis to meet performance or price goals. Soft means the processor core is not fixed in silicon and can be targeted to any FPGA family.

You are not required to create a new processor configuration for every new design. FPGA provides ready-made system designs that you can use as is. If these designs meet your system requirements, there is no need to configure the design further. In addition, you can use the Nios II instruction set simulator to begin writing and debugging Nios II applications before the final hardware configuration is determined.

Flexible Peripheral Set and Address Map

A flexible peripheral set is one of the most notable differences between processor systems and fixed microcontrollers. Because the processor is implemented in programmable logic, you can easily build made-to-order processor systems with the exact peripheral set required for the target applications.

FPGA provides software constructs to access memory and peripherals generically, independently of address location. Therefore, the flexible peripheral set and address map does not affect application developers.

There are two broad classes of peripherals: standard peripherals and custom peripherals.

Standard Peripherals

FPGA provides a set of peripherals commonly used in microcontrollers, such as timers, serial communication interfaces, general-purpose I/O, SDRAM controllers, and other memory interfaces. The list of available peripherals continues to increase as FPGA and third-party vendors release new peripherals.

Related Information

Embedded Peripherals IP User Guide

Custom Components

You can also create custom components and integrate them in processor systems. For performance-critical systems that spend most CPU cycles executing a specific section of code, it is a common technique to create a custom peripheral that implements the same function in hardware.

This approach offers a double performance benefit:

- Hardware implementation is faster than software.
- Processor is free to perform other functions in parallel while the custom peripheral operates on data.

Related Information

Creating Platform Designer Components

Custom Instructions

Like custom peripherals, custom instructions allow you to increase system performance by augmenting the processor with custom hardware. You can achieve significant performance improvements, often on the order of 10 to 100 times, by implementing performance-critical operations in hardware using custom instruction logic.

The custom logic is integrated into the processor's arithmetic logic unit (ALU). Similar to native Nios II instructions, custom instruction logic can take values from up to two source registers and optionally write back a result to a destination register.

Because the processor is implemented on reprogrammable FPGAs, software and hardware engineers can work together to iteratively optimize the hardware and test the results of software running on hardware.

From the software perspective, custom instructions appear as machine-generated assembly macros or C functions, so programmers do not need to understand assembly language to use custom instructions.

Automated System Generation

FPGA's system integration tools fully automate the process of configuring processor features and generating a hardware design that you program in an FPGA device. The graphical user interface (GUI) enables you to configure processor systems with any number of peripherals and memory interfaces. You can create entire processor systems without performing any schematic or HDL design entry. can also import HDL design files, providing an easy mechanism to integrate custom logic in a processor system.

After system generation, you can download the design onto a board, and debug software executing on the board. To the software developer, the processor architecture of the design is set. Software development proceeds in the same manner as for traditional, nonconfigurable processors.

Intel FPGA IP Evaluation Mode

You can evaluate the processor without a license. With FPGA's free feature, you can perform the following actions:

- Simulate the behavior of a processor within your system.
- Verify the functionality of your design, as well as evaluate its size and speed quickly and easily.
- Generate time-limited device programming files for designs that include processors.
- Program a device and verify your design in hardware.

You only need to purchase a license for the processor when you are completely satisfied with its functionality and performance, and want to take your design to production.

May 2004	1.0	Initial release.

Processor Architecture 2

2016.10.28

NII51002

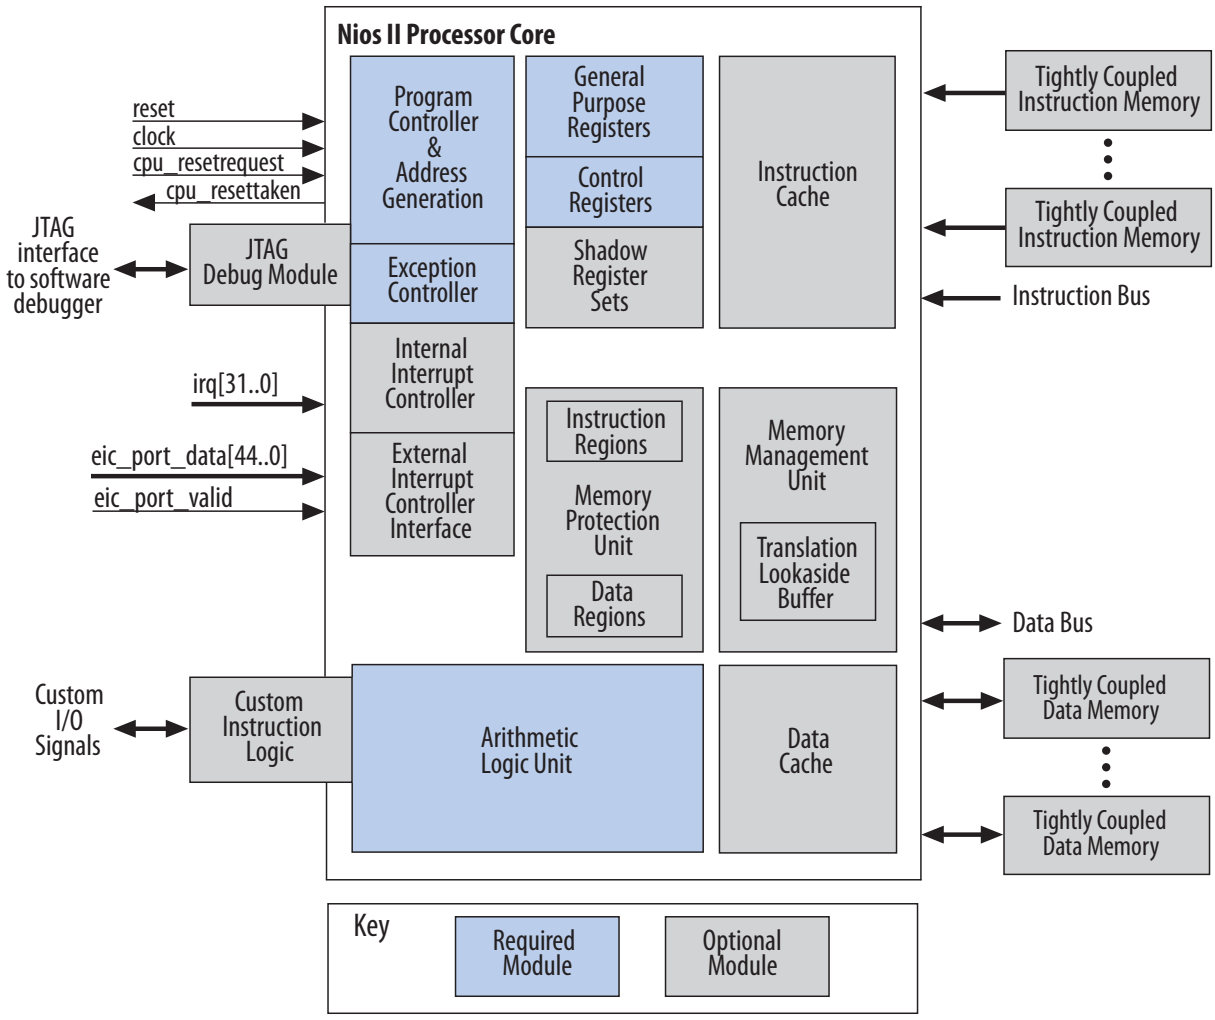
This chapter describes the hardware structure of the processor, including a discussion of all the functional units of the Nios II architecture and the fundamentals of the processor hardware implementation.

The Nios II architecture describes an instruction set architecture (ISA). The ISA in turn necessitates a set of functional units that implement the instructions. A processor core is a hardware design that implements the Nios II instruction set and supports the functional units described in this document. The processor core does not include peripherals or the connection logic to the outside world. It includes only the circuits required to implement the Nios II architecture.

The Nios II architecture defines the following functional units:

- Register file
- Arithmetic logic unit (ALU)
- Interface to custom instruction logic
- Exception controller
- Internal or external interrupt controller
- Instruction bus
- Data bus
- Memory management unit (MMU)
- Memory protection unit (MPU)
- Instruction and data cache memories
- Tightly-coupled memory interfaces for instructions and data
- JTAG debug module

Figure 2-1: Processor Core Block Diagram



Processor Implementation

The functional units of the Nios II architecture form the foundation for the Nios II instruction set. However, this does not indicate that any unit is implemented in hardware. The Nios II architecture describes an instruction set, not a particular hardware implementation. A functional unit can be implemented in hardware, emulated in software, or omitted entirely.

A Nios II implementation is a set of design choices embodied by a particular processor core. All implementations support the instruction set defined in the *Instruction Set Reference* chapter.

Each implementation achieves specific objectives, such as smaller core size or higher performance. This flexibility allows the Nios II architecture to adapt to different target applications.

Implementation variables generally fit one of three trade-off patterns: more or less of a feature; inclusion or exclusion of a feature; hardware implementation or software emulation of a feature. An example of each trade-off follows:

- More or less of a feature—For example, to fine-tune performance, you can increase or decrease the amount of instruction cache memory. A larger cache increases execution speed of large programs, while a smaller cache conserves on-chip memory resources.
- Inclusion or exclusion of a feature—For example, to reduce cost, you can choose to omit the JTAG debug module. This decision conserves on-chip logic and memory resources, but it eliminates the ability to use a software debugger to debug applications.
- Hardware implementation or software emulation—For example, in control applications that rarely perform complex arithmetic, you can choose for the division instruction to be emulated in software. Removing the divide hardware conserves on-chip resources but increases the execution time of division operations.

For information about which cores supports what features, refer to the *Core Implementation Details* chapter of the *Processor Reference Handbook*.

For complete details about user-selectable parameters for the processor, refer to the *Instantiating the Processor* chapter of the *Processor Reference Handbook*.

Register File

The Nios II architecture supports a flat register file, consisting of thirty-two 32-bit general-purpose integer registers, and up to thirty-two 32-bit control registers. The architecture supports supervisor and user modes that allow system code to protect the control registers from errant applications.

The processor can optionally have one or more shadow register sets. A shadow register set is a complete set of Nios II general-purpose registers. When shadow register sets are implemented, the `CRS` field of the `status` register indicates which register set is currently in use. An instruction access to a general-purpose register uses whichever register set is active.

A typical use of shadow register sets is to accelerate context switching. When shadow register sets are implemented, the processor has two special instructions, `rdprs` and `wrprs`, for moving data between register sets. Shadow register sets are typically manipulated by an operating system kernel, and are transparent to application code. A processor can have up to 63 shadow register sets.

The Nios II architecture allows for the future addition of floating-point registers.

For details about shadow register set implementation and usage, refer to "Registers" and "Exception Processing" in the *Programming Model* chapter of the Processor Reference Handbook.

For details about the `rdprs` and `wrprs` instructions, refer to the *Instruction Set Reference* chapter of the *Processor Reference Handbook*.

Related Information

- **Programming Model** on page 3-1
- **Instruction Set Reference** on page 8-1

Arithmetic Logic Unit

The Nios II ALU operates on data stored in general-purpose registers. ALU operations take one or two inputs from registers, and store a result back in a register. The ALU supports the data operations described in the table below. To implement any other operation, software computes the result by performing a combination of the fundamental operations.

Table 2-1: Operations Supported by the Nios II ALU

Category	Details
Arithmetic	The ALU supports addition, subtraction, multiplication, and division on signed and unsigned operands.
Relational	The ALU supports the equal, not-equal, greater-than-or-equal, and less-than relational operations (==, != >=, <) on signed and unsigned operands.
Logical	The ALU supports AND, OR, NOR, and XOR logical operations.
Shift and Rotate	The ALU supports shift and rotate operations, and can shift/rotate data by 0 to 31 bit positions per instruction. The ALU supports arithmetic shift right and logical shift right/left. The ALU supports rotate left/right.

Unimplemented Instructions

Some processor core implementations do not provide hardware to support the entire Nios II instruction set. In such a core, instructions without hardware support are known as unimplemented instructions.

The processor generates an exception whenever it issues an unimplemented instruction so your exception handler can call a routine that emulates the operation in software. Unimplemented instructions do not affect the programmer's view of the processor.

For a list of potential unimplemented instructions, refer to the *Programming Model* chapter of the Processor Reference Handbook.

Related Information

Programming Model on page 3-1

Custom Instructions

The Nios II architecture supports user-defined custom instructions. The Nios II ALU connects directly to custom instruction logic, enabling you to implement operations in hardware that are accessed and used exactly like native instructions.

Refer to "Custom Instruction Tab" in the *Instantiating the Processor* chapter of the *Processor Reference Handbook* for additional information.

Related Information

Nios II Custom Instruction User Guide

Reset and Debug Signals

The table below describes the reset and debug signals that the processor core supports.

Table 2-2: Processor Debug and Reset Signals

Signal Name	Type	Purpose
reset	Reset	This is a global hardware reset signal that forces the processor core to reset immediately.
cpu_resetrequest	Reset	This is an optional, local reset signal that causes the processor to reset without affecting other components in the system. The processor finishes executing any instructions in the pipeline, and then enters the reset state. This process can take several clock cycles, so be sure to continue asserting the cpu_resetrequest signal until the processor core asserts a cpu_resettaken signal. The processor core asserts a cpu_resettaken signal for 1 cycle when the reset is complete and then periodically if cpu_resetrequest remains asserted. The processor remains in the reset state for as long as cpu_resetrequest is asserted. While the processor is in the reset state, it periodically reads from the reset address. It discards the result of the read, and remains in the reset state. The processor does not respond to cpu_resetrequest when the processor is under the control of the JTAG debug module, that is, when the processor is paused. The processor responds to the cpu_resetrequest signal if the signal is asserted when the JTAG debug module relinquishes control, both momentarily during each single step as well as when you resume execution.
debug_reset_request	Reset	This reset output signal appears when the JTAG Debug module is enabled. This signal is triggered by the JTAG debugger or nios2-download -r command. This signal must be connected to the reset input signal of the processor which allows the JTAG debugger to reset the processor. This signal can be connected to the reset input signal of other components when needed.
debugreq	Debug	This is an optional signal that temporarily suspends the processor for debugging purposes. When you assert the signal, the processor pauses in the same manner as when a breakpoint is encountered, transfers execution to the routine located at the break address, and asserts a debugack signal. Asserting the debugreq signal when the processor is already paused has no effect.
reset_req	Reset	This optional signal prevents the memory corruption by performing a reset handshake before the processor resets.

For more information about adding reset signals and debug signals to the processor, refer to **Advanced Features Tab** and **JTAG Debug Module Tab** in the *Instantiating the Processor* chapter respectively.

Exception and Interrupt Controllers

The processor includes hardware for handling exceptions, including hardware interrupts. It also includes an optional external interrupt controller (EIC) interface. The EIC interface enables you to speed up interrupt handling in a complex system by adding a custom interrupt controller.

Exception Controller

The Nios II architecture provides a simple, nonvectored exception controller to handle all exception types. Each exception, including internal hardware interrupts, causes the processor to transfer execution to an exception address. An exception handler at this address determines the cause of the exception and dispatches an appropriate exception routine.

Exception addresses are specified with the Processor parameter editor.

All exceptions are precise. Precise means that the processor has completed execution of all instructions preceding the faulting instruction and not started execution of instructions following the faulting instruction. Precise exceptions allow the processor to resume program execution once the exception handler clears the exception.

EIC Interface

An EIC provides high performance hardware interrupts to reduce your program's interrupt latency. An EIC is typically used in conjunction with shadow register sets and when you need more than the 32 interrupts provided by the Nios II internal interrupt controller.

The processor connects to an EIC through the EIC interface. When an EIC is present, the internal interrupt controller is not implemented; connects interrupts to the EIC.

The EIC selects among active interrupts and presents one interrupt to the processor, with interrupt handler address and register set selection information. The interrupt selection algorithm is specific to the EIC implementation, and is typically based on interrupt priorities. The processor does not depend on any specific interrupt prioritization scheme in the EIC.

For every external interrupt, the EIC presents an interrupt level. The processor uses the interrupt level in determining when to service the interrupt.

Any external interrupt can be configured as an NMI. NMIs are not masked by the `status.PIE` bit, and have no interrupt level.

An EIC can be software-configurable.

Note: When the EIC interface and shadow register sets are implemented on the Nios II core, you must ensure that your software is built with the Nios II EDS version 9.0 or higher. Earlier versions have an implementation of the `eret` instruction that is incompatible with shadow register sets.

For a typical example of an EIC, refer to the *Vectored Interrupt Controller* chapter in the Embedded Peripherals IP User Guide.

For details about EIC usage, refer to "Exception Processing" in the *Programming Model* chapter of the *Processor Reference Handbook*.

Related Information

- **Embedded Peripherals IP User Guide**
  For a typical example of an EIC, refer to the *Vectored Interrupt Controller* chapter in the *Embedded Peripherals IP User Guide*.
- **Programming Model** on page 3-1

Internal Interrupt Controller

The Nios II architecture supports 32 internal hardware interrupts. The processor core has 32 level-sensitive interrupt request (IRQ) inputs, `irq0` through `irq31`, providing a unique input for each interrupt source. IRQ priority is determined by software. The architecture supports nested interrupts.

Your software can enable and disable any interrupt source individually through the `ienable` control register, which contains an interrupt-enable bit for each of the IRQ inputs. Software can enable and disable interrupts globally using the PIE bit of the `status` control register. A hardware interrupt is generated if and only if all of the following conditions are true:

- The PIE bit of the `status` register is 1
- An interrupt-request input, `irq<n>`, is asserted
- The corresponding bit n of the `ienable` register is 1

The interrupt vector custom instruction is less efficient than using the EIC interface with the FPGA vectored interrupt controller component, and thus is deprecated in . recommends using the EIC interface.

Memory and I/O Organization

This section explains hardware implementation details of the Nios II memory and I/O organization. The discussion covers both general concepts true of all processor systems, as well as features that might change from system to system.

The flexible nature of the Nios II memory and I/O organization are the most notable difference between processor systems and traditional microcontrollers. Because processor systems are configurable, the memories and peripherals vary from system to system. As a result, the memory and I/O organization varies from system to system.

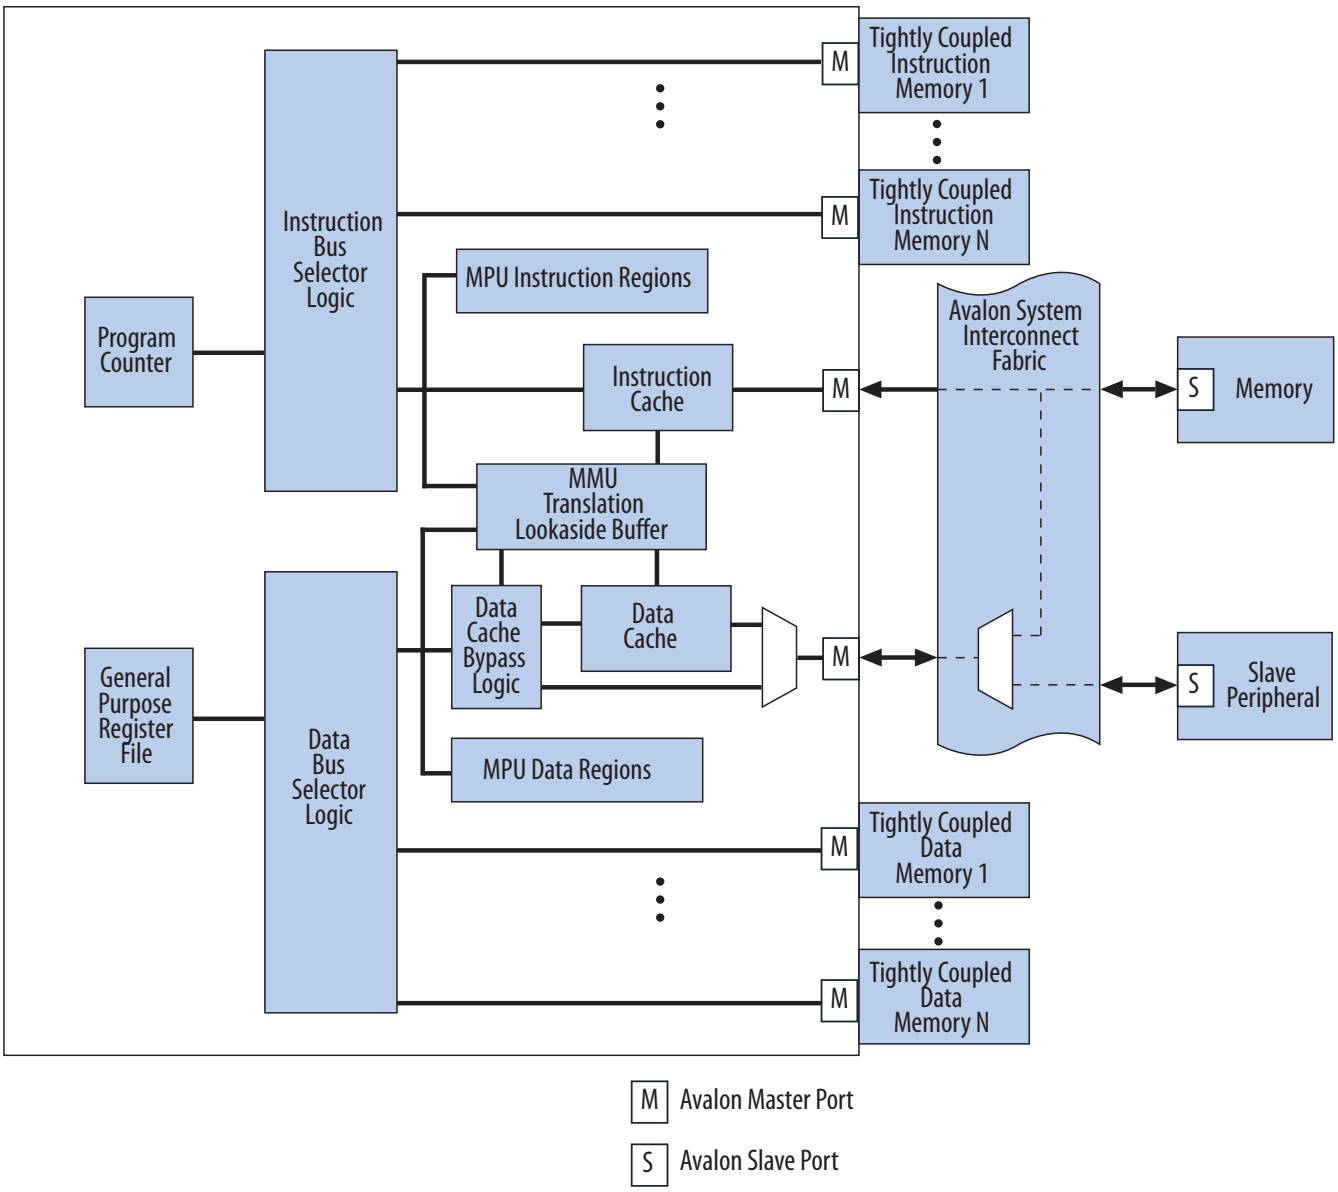
A Nios II core uses one or more of the following to provide memory and I/O access:

- Instruction master port—An ® Memory-Mapped (-MM) master port that connects to instruction memory via system interconnect fabric
- Instruction cache—Fast cache memory internal to the Nios II core
- Data master port—An -MM master port that connects to data memory and peripherals via system interconnect fabric
- Data cache—Fast cache memory internal to the Nios II core
- Tightly-coupled instruction or data memory port—Interface to fast on-chip memory outside the Nios II core

The Nios II architecture handles the hardware details for the programmer, so programmers can develop Nios II applications without specific knowledge of the hardware implementation.

For details that affect programming issues, refer to the *Programming Model* chapter of the *Processor Reference Handbook*.

Figure 2-2: Nios II Memory and I/O Organization



Related Information

Programming Model on page 3-1

Instruction and Data Buses

The Nios II architecture supports separate instruction and data buses, classifying it as a Harvard architecture. Both the instruction and data buses are implemented as -MM master ports that adhere to the -MM interface specification. The data master port connects to both memory and peripheral components, while the instruction master port connects only to memory components.

Note: The instruction and data masters have a combined address map. The memory model is arranged so that instructions and data are in the same address space.

Related Information

Avalon Interface Specifications
Refer to the Avalon Interface Specifications for details of the Avalon-MM interface.

Memory and Peripheral Access

The Nios II architecture provides memory-mapped I/O access. Both data memory and peripherals are mapped into the address space of the data master port. The Nios II architecture uses little-endian byte ordering. Words and halfwords are stored in memory with the more-significant bytes at higher addresses.

The Nios II architecture does not specify anything about the existence of memory and peripherals; the quantity, type, and connection of memory and peripherals are system-dependent. Typically, processor systems contain a mix of fast on-chip memory and slower off-chip memory. Peripherals typically reside on-chip, although interfaces to off-chip peripherals also exist.

Instruction Master Port

The Nios II instruction bus is implemented as a 32-bit -MM master port. The instruction master port performs a single function: it fetches instructions to be executed by the processor. The instruction master port does not perform any write operations.

The instruction master port is a pipelined -MM master port. Support for pipelined -MM transfers minimizes the impact of synchronous memory with pipeline latency and increases the overall f_{MAX} of the system. The instruction master port can issue successive read requests before data has returned from prior requests. The processor can prefetch sequential instructions and perform branch prediction to keep the instruction pipe as active as possible.

The instruction master port always retrieves 32 bits of data. The instruction master port relies on dynamic bus-sizing logic contained in the system interconnect fabric. By virtue of dynamic bus sizing, every instruction fetch returns a full instruction word, regardless of the width of the target memory. Consequently, programs do not need to be aware of the widths of memory in the processor system.

The Nios II architecture supports on-chip cache memory for improving average instruction fetch performance when accessing slower memory. Refer to the "Cache Memory" section of this chapter for details.

The Nios II architecture supports tightly-coupled memory, which provides guaranteed low-latency access to on-chip memory. Refer to the "Tightly-Coupled Memory" section of this chapter for details.

Related Information

- **Cache Memory** on page 2-10
- **Tightly-Coupled Memory** on page 2-12

Data Master Port

The Nios II data bus is implemented as a 32-bit -MM master port. The data master port performs two functions:

- Read data from memory or a peripheral when the processor executes a load instruction
- Write data to memory or a peripheral when the processor executes a store instruction

Byte-enable signals on the master port specify which of the four byte-lane(s) to write during store operations. When the Nios II core is configured with a data cache line size greater than four bytes, the data master port supports pipelined -MM transfers. When the data cache line size is only four bytes, any memory pipeline latency is perceived by the data master port as wait states. Load and store operations can complete in a single clock cycle when the data master port is connected to zero-wait-state memory.

The Nios II architecture supports on-chip cache memory for improving average data transfer performance when accessing slower memory. Refer to the "Cache Memory" section of this chapter for details.

The Nios II architecture supports tightly-coupled memory, which provides guaranteed low-latency access to on-chip memory. Refer to "Tightly-Coupled Memory" section of this chapter for details.

- Read data from memory or a peripheral when the processor executes a load instruction
- Write data to memory or a peripheral when the processor executes a store instruction

Byte-enable signals on the master port specify which of the four byte-lane(s) to write during store operations. Load and store operations can complete in a single clock cycle when the data master port is connected to zero-wait-state memory.

Note: only supports a fixed 32-byte linesize for data cache.

The Nios II architecture supports on-chip cache memory for improving average data transfer performance when accessing slower memory. Refer to the "Cache Memory" section of this chapter for details.

The Nios II architecture supports tightly-coupled memory, which provides guaranteed low-latency access to on-chip memory. Refer to "Tightly-Coupled Memory" section of this chapter for details.

Related Information

- **Cache Memory** on page 2-10
- **Tightly-Coupled Memory** on page 2-12

Shared Memory for Instructions and Data

Usually the instruction and data master ports share a single memory that contains both instructions and data. While the processor core has separate instruction and data buses, the overall processor system might present a single, shared instruction/data bus to the outside world. The outside view of the processor system depends on the memory and peripherals in the system and the structure of the system interconnect fabric.

The data and instruction master ports never cause a gridlock condition in which one port starves the other. For highest performance, assign the data master port higher arbitration priority on any memory that is shared by both instruction and data master ports.

Cache Memory

The Nios II architecture supports cache memories on both the instruction master port (instruction cache) and the data master port (data cache). Cache memory resides on-chip as an integral part of the processor core. The cache memories can improve the average memory access time for processor systems that use slow off-chip memory such as SDRAM for program and data storage.

The instruction and data caches are enabled perpetually at run-time, but methods are provided for software to bypass the data cache so that peripheral accesses do not return cached data. Cache management and cache coherency are handled by software. The Nios II instruction set provides instructions for cache management.

Configurable Cache Memory Options

The cache memories are optional. The need for higher memory performance (and by association, the need for cache memory) is application dependent. Many applications require the smallest possible processor core, and can trade-off performance for size.

A processor core might include one, both, or neither of the cache memories. Furthermore, for cores that provide data as well as instruction cache, the sizes of the cache memories are user-configurable. The inclusion of cache memory does not affect the functionality of programs, but it does affect the speed at which the processor fetches instructions and reads/writes data.

Effective Use of Cache Memory

The effectiveness of cache memory to improve performance is based on the following premises:

- Regular memory is located off-chip, and access time is long compared to on-chip memory
- The largest, performance-critical instruction loop is smaller than the instruction cache
- The largest block of performance-critical data is smaller than the data cache

Optimal cache configuration is application specific, although you can make decisions that are effective across a range of applications. For example, if a processor system includes only fast, on-chip memory (i.e., it never accesses slow, off-chip memory), an instruction or data cache is unlikely to offer any performance gain. As another example, if the critical loop of a program is 2 KB, but the size of the instruction cache is 1 KB, an instruction cache does not improve execution speed. In fact, an instruction cache may degrade performance in this situation.

If an application always requires certain data or sections of code to be located in cache memory for performance reasons, the tightly-coupled memory feature might provide a more appropriate solution. Refer to the "Tightly-Coupled Memory" section for details.

Cache Bypass Methods

The Nios II architecture provides the following methods for bypassing the data cache:

- I/O load and store instructions
- Bit-31 cache bypass

The Nios II architecture provides the following methods for bypassing the data cache:

- I/O load and store instructions
- Bit-31 cache bypass
- Peripheral Region

Note: By default the Bit-31 cache bypass is turned on.

I/O Load and Store Instructions Method

The load and store I/O instructions such as `ldwio` and `stwio` bypass the data cache and force an -MM data transfer to a specified address.

The Bit-31 Cache Bypass Method

The bit-31 cache bypass method on the data master port uses bit 31 of the address as a tag that indicates whether the processor should transfer data to/from cache, or bypass it. This is a convenience for software, which might need to cache certain addresses and bypass others. Software can pass addresses as parameters between functions, without having to specify any further information about whether the addressed data is cached or not.

To determine which cores implement which cache bypass methods, refer to the *Nios II Core Implementation Details* chapter of the *Processor Reference Handbook*.

Related Information

Core Implementation Details on page 5-1

Peripheral Region

cores optionally support a new peripheral region mechanism to indicate cacheability. The peripheral region cacheability mechanism allows a user at generation time to specify a region of address space that is treated as non-cacheable. The peripheral region is any integer power of 2 bytes from a minimum of 4096

bytes up to a maximum of 2 GBytes and must be located at a base address aligned to the size of the peripheral region. The peripheral region is available as long as an MMU is not present.

Tightly-Coupled Memory

Tightly-coupled memory provides guaranteed low-latency memory access for performance-critical applications. Compared to cache memory, tightly-coupled memory provides the following benefits:

- Performance similar to cache memory
- Software can guarantee that performance-critical code or data is located in tightly-coupled memory
- No real-time caching overhead, such as loading, invalidating, or flushing memory

Physically, a tightly-coupled memory port is a separate master port on the processor core, similar to the instruction or data master port. A Nios II core can have zero, one, or multiple tightly-coupled memories. The Nios II architecture supports tightly-coupled memory for both instruction and data access. Each tightly-coupled memory port connects directly to exactly one memory with guaranteed low, fixed latency. The memory is external to the Nios II core and is located on chip.

Accessing Tightly-Coupled Memory

Tightly-coupled memories occupy normal address space, the same as other memory devices connected via system interconnect fabric. The address ranges for tightly-coupled memories (if any) are determined at system generation time.

Software accesses tightly-coupled memory using regular load and store instructions. From the software's perspective, there is no difference accessing tightly-coupled memory compared to other memory.

Note: The tightly-coupled master requires a fixed memory latency of 1 cycle. Hence, the transaction with a slave in a different clock domain may not be successful since the transfer would take more than 1 cycle.

Effective Use of Tightly-Coupled Memory

A system can use tightly-coupled memory to achieve maximum performance for accessing a specific section of code or data. For example, interrupt-intensive applications can place exception handler code into a tightly-coupled memory to minimize interrupt latency. Similarly, compute-intensive digital signal processing (DSP) applications can place data buffers into tightly-coupled memory for the fastest possible data access.

If the application's memory requirements are small enough to fit entirely on chip, it is possible to use tightly-coupled memory exclusively for code and data. Larger applications must selectively choose what to include in tightly-coupled memory to maximize the cost-performance trade-off.

For additional tightly-coupled memory guidelines.

Address Map

The address map for memories and peripherals in a processor system is design dependent. You specify the address map in .

There are three addresses that are part of the processor and deserve special mention:

- Reset address
- Exception address
- Break handler address

Programmers access memories and peripherals by using macros and drivers. Therefore, the flexible address map does not affect application developers.

Memory Management Unit

The optional Nios II MMU provides the following features and functionality:

- Virtual to physical address mapping
- Memory protection
- 32-bit virtual and physical addresses, mapping a 4-GB virtual address space into as much as 4 GB of physical memory
- 4-KB page and frame size
- Low 512 MB of physical address space available for direct access
- Hardware translation lookaside buffers (TLBs), accelerating address translation
  - Separate TLBs for instruction and data accesses
  - Read, write, and execute permissions controlled per page
  - Default caching behavior controlled per page
  - TLBs acting as n-way set-associative caches for software page tables
  - TLB sizes and associativities configurable in the Processor parameter editor
- Format of page tables (or equivalent data structures) determined by system software
- Replacement policy for TLB entries determined by system software
- Write policy for TLB entries determined by system software

For more information about the MMU implementation, refer to the *Programming Model* chapter of the *Processor Reference Handbook*.

You can optionally include the MMU when you instantiate the processor in your hardware system. When present, the MMU is always enabled, and the data and instruction caches are virtually-indexed, physically-tagged caches. Several parameters are available, allowing you to optimize the MMU for your system needs.

For complete details about user-selectable parameters for the Nios II MMU, refer to the *Instantiating the Processor* chapter of the *Processor Reference Handbook*.

Note: The Nios II MMU is optional and mutually exclusive from the Nios II MPU. systems can include either an MMU or MPU, but cannot include both an MMU and MPU on the same processor core.

Programming Model on page 3-1

Memory Protection Unit

The optional Nios II MPU provides the following features and functionality:

- Memory protection
- Up to 32 instruction regions and 32 data regions
- Variable instruction and data region sizes
- Amount of region memory defined by size or upper address limit
- Read and write access permissions for data regions
- Execute access permissions for instruction regions
- Overlapping regions

For more information about the MPU implementation, refer to the *Programming Model* chapter of the *Processor Reference Handbook*.

You can optionally include the MPU when you instantiate the processor in your hardware system. When present, the MPU is always enabled. Several parameters are available, allowing you to optimize the MPU for your system needs.

For complete details about user-selectable parameters for the Nios II MPU, refer to the *Instantiating the Processor* chapter of the *Processor Reference Handbook*.

Note: The Nios II MPU is optional and mutually exclusive from the Nios II MMU. systems can include either an MPU or MMU, but cannot include both an MPU and MMU on the same processor core.

Programming Model on page 3-1

JTAG Debug Module

The Nios II architecture supports a JTAG debug module that provides on-chip emulation features to control the processor remotely from a host PC. PC-based software debugging tools communicate with the JTAG debug module and provide facilities, such as the following features:

- Downloading programs to memory
- Starting and stopping execution
- Setting breakpoints and watchpoints
- Analyzing registers and memory
- Collecting real-time execution trace data

Note: The Nios II MMU does not support the JTAG debug module trace.

The debug module connects to the JTAG circuitry in an FPGA. External debugging probes can then access the processor via the standard JTAG interface on the FPGA. On the processor side, the debug module connects to signals inside the processor core. The debug module has nonmaskable control over the processor, and does not require a software stub linked into the application under test. All system resources visible to the processor in supervisor mode are available to the debug module. For trace data collection, the debug module stores trace data in memory either on-chip or in the debug probe.

The debug module gains control of the processor either by asserting a hardware break signal, or by writing a break instruction into program memory to be executed. In both cases, the processor transfers execution to the routine located at the break address. The break address is specified with the Processor parameter editor in .

Soft processor cores such as the processor offer unique debug capabilities beyond the features of traditional, fixed processors. The soft nature of the processor allows you to debug a system in development using a full-featured debug core, and later remove the debug features to conserve logic resources. For the release version of a product, the JTAG debug module functionality can be reduced, or removed altogether.

The following sections describe the capabilities of the Nios II JTAG debug module hardware. The usage of all hardware features is dependent on host software, such as the Nios II Software Build Tools for Eclipse, which manages the connection to the target processor and controls the debug process.

JTAG Target Connection

The JTAG target connection provides the ability to connect to the processor through the standard JTAG pins on the FPGA. This provides basic capabilities to start and stop the processor, and examine and edit registers and memory. The JTAG target connection is the minimum requirement for the Nios II flash programmer.

Note: While the processor has no minimum clock frequency requirements, recommends that your design's system clock frequency be at least four times the JTAG clock frequency to ensure that the on-chip instrumentation (OCI) core functions properly.

Download and Execute Software

Downloading software refers to the ability to download executable code and data to the processor's memory via the JTAG connection. After downloading software to memory, the JTAG debug module can then exit debug mode and transfer execution to the start of executable code.

Software Breakpoints

Software breakpoints allow you to set a breakpoint on instructions residing in RAM. The software breakpoint mechanism writes a break instruction into executable code stored in RAM. When the processor executes the break instruction, control is transferred to the JTAG debug module.

Hardware Breakpoints

Hardware breakpoints allow you to set a breakpoint on instructions residing in nonvolatile memory, such as flash memory. The hardware breakpoint mechanism continuously monitors the processor's current instruction address. If the instruction address matches the hardware breakpoint address, the JTAG debug module takes control of the processor.

Hardware breakpoints are implemented using the JTAG debug module's hardware trigger feature.

Hardware Triggers

Hardware triggers activate a debug action based on conditions on the instruction or data bus during real-time program execution. Triggers can do more than halt processor execution. For example, a trigger can be used to enable trace data collection during real-time processor execution.

Hardware trigger conditions are based on either the instruction or data bus. Trigger conditions on the same bus can be logically ANDed, enabling the JTAG debug module to trigger, for example, only on write cycles to a specific address.

Table 2-3: Trigger Conditions

Condition	Bus	Description
Specific address	Data, Instruction	Trigger when the bus accesses a specific address.
Specific data value	Data	Trigger when a specific data value appears on the bus.
Read cycle	Data	Trigger on a read bus cycle.
Write cycle	Data	Trigger on a write bus cycle.
Armed	Data, Instruction	Trigger only after an armed trigger event. Refer to the Armed Triggers section.
Range	Data	Trigger on a range of address values, data values, or both. Refer to the Triggering on Ranges of Values section.

When a trigger condition occurs during processor execution, the JTAG debug module triggers an action, such as halting execution, or starting trace capture. The table below lists the trigger actions supported by the Nios II JTAG debug module.

Table 2-4: Trigger Actions

Action	Description
Break	Halt execution and transfer control to the JTAG debug module.
External trigger	Assert a trigger signal output. This trigger output can be used, for example, to trigger an external logic analyzer.
Trace on	Turn on trace collection.
Trace off	Turn off trace collection.
Trace sample	Store one sample of the bus to trace buffer.
Arm	Enable an armed trigger.

Note: For the *Trace sample* triger action, only conditions on the data bus can trigger this action.

Armed Triggers

The JTAG debug module provides a two-level trigger capability, called armed triggers. Armed triggers enable the JTAG debug module to trigger on event B, only after event A. In this example, event A causes a trigger action that enables the trigger for event B.

Triggering on Ranges of Values

The JTAG debug module can trigger on ranges of data or address values on the data bus. This mechanism uses two hardware triggers together to create a trigger condition that activates on a range of values within a specified range.

Trace Capture

Trace capture refers to ability to record the instruction-by-instruction execution of the processor as it executes code in real-time. The JTAG debug module offers the following trace features:

- Capture execution trace (instruction bus cycles).
- Capture data trace (data bus cycles).
- For each data bus cycle, capture address, data, or both.
- Start and stop capturing trace in real time, based on triggers.
- Manually start and stop trace under host control.
- Optionally stop capturing trace when trace buffer is full, leaving the processor executing.
- Store trace data in on-chip memory buffer in the JTAG debug module. (This memory is accessible only through the JTAG connection.)
- Store trace data to larger buffers in an off-chip debug probe.

Certain trace features require additional licensing or debug tools from third-party debug providers. For example, an on-chip trace buffer is a standard feature of the processor, but using an off-chip trace buffer requires additional debug software and hardware provided by Imagination Technologies™, LLC or Lauterbach GmbH.

Lauterbach.com
For more information, refer to the Lauterbach GmbH website.

Execution vs. Data Trace

The JTAG debug module supports tracing the instruction bus (execution trace), the data bus (data trace), or both simultaneously. Execution trace records only the addresses of the instructions executed, enabling you to analyze where in memory (that is, in which functions) code executed. Data trace records the data associated with each load and store operation on the data bus.

The JTAG debug module can filter the data bus trace in real time to capture the following:

- Load addresses only
- Store addresses only
- Both load and store addresses
- Load data only
- Load address and data
- Store address and data
- Address and data for both loads and stores
- Single sample of the data bus upon trigger event

Trace Frames

A frame is a unit of memory allocated for collecting trace data. However, a frame is not an absolute measure of the trace depth.

To keep pace with the processor executing in real time, execution trace is optimized to store only selected addresses, such as branches, calls, traps, and interrupts. From these addresses, host-side debug software can later reconstruct an exact instruction-by-instruction execution trace. Furthermore, execution trace data is stored in a compressed format, such that one frame represents more than one instruction. As a result of these optimizations, the actual start and stop points for trace collection during execution might vary slightly from the user-specified start and stop points.

Data trace stores 100% of requested loads and stores to the trace buffer in real time. When storing to the trace buffer, data trace frames have lower priority than execution trace frames. Therefore, while data frames are always stored in chronological order, execution and data trace are not guaranteed to be exactly synchronized with each other.

Processor Architecture Revision History

Document Version	Changes
2019.05.20	*Reset and Debug Signals*: Added definition for the `debug_reset_request` signal.
2019.04.30	Maintenance release

2018.04.18	• Implemented editorial enhancements.
	• Removed the following sections:
	  • Introduction to Nios II Floating Point Custom Instructions
	  • Nios II Floating Point Hardware 2 Component
	  • Nios II Floating Point Hardware (FPH1) Component
	Instead, refer to the *Nios II Custom Instruction User Guide*.

2016.10.28	Maintenance release

Document Version	Changes
2015.04.02	Initial release

Table 2-5: Document Revision History

Date	Version	Changes
April 2015	2015.04.02	Maintenance release.
February 2014	13.1.0	• Added information on ECC support. • Added information on enhanced floating-point custom instructions. • Removed HardCopy information. • Removed references to SOPC Builder.
May 2011	11.0.0	• Added references to new system integration tool. • Moved interrupt vector custom instruction information to the *Instantiating the Processor* chapter.
December 2010	10.1.0	Added reference to tightly-coupled memory tutorial.
July 2010	10.0.0	Maintenance release.
November 2009	9.1.0	• Added external interrupt controller interface information. • Added shadow register set information.
March 2009	9.0.0	Maintenance release.
November 2008	8.1.0	• Expanded floating-point instructions information. • Updated description of optional `cpu_resetrequest` and `cpu_resettaken` signals. • Added description of optional `debugreq` and `debugack` signals.
May 2008	8.0.0	Added MMU and MPU sections.
October 2007	7.2.0	Maintenance release.
May 2007	7.1.0	• Added table of contents to Introduction section. • Added Referenced Documents section.
March 2007	7.0.0	Maintenance release.
November 2006	6.1.0	Described interrupt vector custom instruction.
May 2006	6.0.0	• Added description of optional `cpu_resetrequest` and `cpu_resettaken`. • Added section on single precision floating-point instructions.
October 2005	5.1.0	Maintenance release.
May 2005	5.0.0	Added tightly-coupled memory.

Date	Version	Changes
December 2004	1.2	Added new control register `ctl5`.
September 2004	1.1	Updates for Nios II 1.01 release.
May 2004	1.0	Initial release.

Programming Model 3

2016.10.28

Subscribe Send Feedback

This chapter describes the Nios® II programming model, covering processor features at the assembly language level. Fully understanding the contents of this chapter requires prior knowledge of computer architecture, operating systems, virtual memory and memory management, software processes and process management, exception handling, and instruction sets. This chapter assumes you have a detailed understanding of these concepts and focuses on how these concepts are specifically implemented in the processor. Where possible, this chapter uses industry-standard terminology.

Note: Because of the flexibility and capability range of the processor, this chapter covers topics that support a variety of operating systems and runtime environments. While reading, be aware that all sections might not apply to you. For example, if you are using a minimal system runtime environment, you can ignore the sections covering operating modes, the MMU, the MPU, or the control registers exclusively used by the MMU and MPU.

Related Information

Nios II Software Developer's Handbook

High-level software development tools are not discussed here. Refer to the Nios II Software Developer's Handbook for information about developing software.

Operating Modes

Operating modes control how the processor operates, manages system memory, and accesses peripherals. The Nios II architecture supports these operating modes:

- Supervisor mode
- User mode

The following sections define the modes, their relationship to your system software and application code, and their relationship to the Nios II MMU and Nios II MPU.

Supervisor Mode

Supervisor mode allows unrestricted operation of the processor. All code has access to all processor instructions and resources. The processor may perform any operation the Nios II architecture provides. Any instruction may be executed, any I/O operation may be initiated, and any area of memory may be accessed.

Operating systems and other system software run in supervisor mode. In systems with an MMU, application code runs in user mode, and the operating system, running in supervisor mode, controls the applica-

tion's access to memory and peripherals. In systems with an MPU, your system software controls the mode in which your application code runs. In systems without an MMU or MPU, all application and system code runs in supervisor mode.

Code that needs direct access to and control of the processor runs in supervisor mode. For example, the processor enters supervisor mode whenever a processor exception (including processor reset or break) occurs. Software debugging tools also use supervisor mode to implement features such as breakpoints and watchpoints.

Note: For systems without an MMU or MPU, all code runs in supervisor mode.

User Mode

User mode is available only when the processor in your hardware design includes an MMU or MPU. User mode exists solely to support operating systems. Operating systems (that make use of the processor's user mode) run your application code in user mode. The user mode capabilities of the processor are a subset of the supervisor mode capabilities. Only a subset of the instruction set is available in user mode.

The operating system determines which memory addresses are accessible to user mode applications. Attempts by user mode applications to access memory locations without user access enabled are not permitted and cause an exception. Code running in user mode uses system calls to make requests to the operating system to perform I/O operations, manage memory, and access other system functionality in the supervisor memory.

The Nios II MMU statically divides the 32-bit virtual address space into user and supervisor partitions. Refer to Address Space and Memory Partitions section for more information about the MMU memory partitions. The MMU provides operating systems access permissions on a per-page basis. Refer to Virtual Addressing for more information about MMU pages.

The Nios II MPU supervisor and user memory divisions are determined by the operating system or runtime environment. The MPU provides user access permissions on a region basis. Refer to Memory Regions for more information about MPU regions.

Memory Management Unit

The processor provides an MMU to support full-featured operating systems. Operating systems that require virtual memory rely on an MMU to manage the virtual memory. When present, the MMU manages memory accesses including translation of virtual addresses to physical addresses, memory protection, cache control, and software process memory allocation.

Recommended Usage

Including the Nios II MMU in your hardware system is optional. The MMU is only useful with an operating system that takes advantage of it.

Many systems have simpler requirements where minimal system software or a small-footprint operating system (such as the FPGA® hardware abstraction library (HAL) or a third party real-time operating system) is sufficient. Such software is unlikely to function correctly in a hardware system with an MMU-based processor. Do not include an MMU in your system unless your operating system requires it.

Note: The FPGA HAL and HAL-based real-time operating systems do not support the MMU.

If your system needs memory protection, but not virtual memory management, refer to Memory Protection Unit section.

Related Information

Memory Protection Unit on page 3-7

Memory Management

Memory management comprises two key functions:

- Virtual addressing—Mapping a virtual memory space into a physical memory space
- Memory protection—Allowing access only to certain memory under certain conditions

Virtual Addressing

A virtual address is the address that software uses. A physical address is the address which the hardware outputs on the address lines of the ® bus. The Nios II MMU divides virtual memory into 4-KB pages and physical memory into 4-KB frames.

The MMU contains a hardware translation lookaside buffer (TLB). The operating system is responsible for creating and maintaining a page table (or equivalent data structures) in memory. The hardware TLB acts as a software managed cache for the page table. The MMU does not perform any operations on the page table, such as hardware table walks. Therefore the operating system is free to implement its page table in any appropriate manner.

There is a 20 bit virtual page number (VPN) and a 12 bit page offset.

Table 3-1: MMU Virtual Address Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Virtual Page Number															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Virtual Page Number				Page Offset											

As input, the TLB takes a VPN plus a process identifier (to guarantee uniqueness). As output, the TLB provides the corresponding physical frame number (PFN).

Distinct processes can use the same virtual address space. The process identifier, concatenated with the virtual address, distinguishes identical virtual addresses in separate processes. To determine the physical address, the Nios II MMU translates a VPN to a PFN and then concatenates the PFN with the page offset. The bits in the page offset are not translated.

Memory Protection

The Nios II MMU maintains read, write, and execute permissions for each page. The TLB provides the permission information when translating a VPN. The operating system can control whether or not each process is allowed to read data from, write data to, or execute instructions on each particular page. The MMU also controls whether accesses to each data page are cacheable or uncacheable by default.

Whenever an instruction attempts to access a page that either has no TLB mapping, or lacks the appropriate permissions, the MMU generates an exception. The processor's precise exceptions enable the system software to update the TLB, and then re-execute the instruction if desired.

Memory Protection

The MMU maintains read, write, and execute permissions for each page. The TLB provides the permission information when translating a VPN. The operating system can control whether or not each process is allowed to read data from, write data to, or execute instructions on each particular page. The MMU also controls whether accesses to each data page are cacheable or uncacheable by default.

Whenever an instruction attempts to access a page that either has no TLB mapping, or lacks the appropriate permissions, the MMU generates an exception. The processor's precise exceptions enable the system software to update the TLB, and then re-execute the instruction if desired.

Address Space and Memory Partitions

The MMU provides a 4-GB virtual address space, and is capable of addressing up to 4 GB of physical memory.

Note: The amount of actual physical memory, determined by the configuration of your hardware system, might be less than the available 4 GB of physical address space.

Virtual Memory Address Space

The 4-GB virtual memory space is divided into partitions. The upper 2 GB of memory is reserved for the operating system and the lower 2 GB is reserved for user processes.

Table 3-2: Virtual Memory Partitions

Partition	Virtual Address Range	Used By	Memory Access	User Mode Access	Default Data Cacheability
I/O	0xE0000000–0xFFFFFFFF	Operating system	Bypasses TLB	No	Disabled
Kernel	0xC0000000–0xDFFFFFFF	Operating system	Bypasses TLB	No	Enabled
Kernel MMU	0x80000000–0xBFFFFFFF	Operating system	Uses TLB	No	Set by TLB
User	0x00000000–0x7FFFFFFF	User processes	Uses TLB	Set by TLB	Set by TLB

Note: All partitions except the user partition in the "Virtual Memory Partition" table are supervisor-only partitions.

Each partition has a specific size, purpose, and relationship to the TLB:

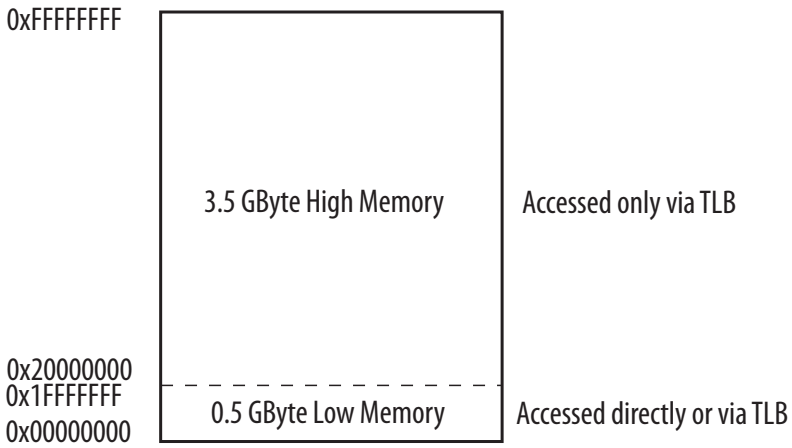
- The 512-MB I/O partition provides access to peripherals.
- The 512-MB kernel partition provides space for the operating system kernel.
- The 1-GB kernel MMU partition is used by the TLB miss handler and kernel processes.
- The 2-GB user partition is used by application processes.

I/O and kernel partitions bypass the TLB. The kernel MMU and user partitions use the TLB. If all software runs in the kernel partition, the MMU is effectively disabled.

Physical Memory Address Space

The 4-GB physical memory is divided into low memory and high memory. The lowest ½ GB of physical address space is low memory. The upper 3½ GB of physical address space is high memory.

Figure 3-1: Division of Physical Memory



High physical memory can only be accessed through the TLB. Any physical address in low memory (29-bits or less) can be accessed through the TLB or by bypassing the TLB. When bypassing the TLB, a 29-bit physical address is computed by clearing the top three bits of the 32-bit virtual address.

Note: To function correctly, the base physical address of all exception vectors (reset, general exception, break, and fast TLB miss) must point to low physical memory so that hardware can correctly map their virtual addresses into the kernel partition. The Processor parameter editor in prevents you from choosing an address outside of low physical memory.

Data Cacheability

Each partition has a rule that determines the default data cacheability property of each memory access. When data cacheability is enabled on a partition of the address space, a data access to that partition can be cached, if a data cache is present in the system. When data cacheability is disabled, all access to that partition goes directly to the switch fabric. Bit 31 is not used to specify data cacheability, as it is in Nios II cores without MMUs. Virtual memory partitions that bypass the TLB have a default data cacheability property, as described in the above table, Virtual Memory Partitions. For partitions that are mapped through the TLB, data cacheability is controlled by the TLB on a per-page basis.

Non-I/O load and store instructions use the default data cacheability property. I/O load and store instructions are always noncacheable, so they ignore the default data cacheability property.

TLB Organization

A TLB functions as a cache for the operating system's page table. In processors with an MMU, one main TLB is shared by instruction and data accesses. The TLB is stored in on-chip RAM and handles translations for instruction fetches and instructions that perform data accesses.

The TLB is organized as an n-way set-associative cache. The software specifies the way (set) when loading a new entry.

Note: You can configure the number of TLB entries and the number of ways (set associativity) of the TLB with the Processor parameter editor in . By default, the TLB is a 16-way cache. The default number of entries depends on the target device, as follows:

- Cyclone III®, Stratix III®, Stratix IV—256 entries, requiring one M9K RAM

  For more information, refer to the *Instantiating the Processor* chapter of the *Processor Reference Handbook*.

The operating system software is responsible for guaranteeing that multiple TLB entries do not map the same virtual address. The hardware behavior is undefined when multiple entries map the same virtual address.

Each TLB entry consists of a tag and data portion. This is analogous to the tag and data portion of instruction and data caches.

Refer to the *Nios II Core Implementation Details* chapter of the *Processor Reference Handbook* for information about instruction and data caches.

The tag portion of a TLB entry contains information used when matching a virtual address to a TLB entry.

Table 3-3: TLB Tag Portion Contents

Field Name	Description
VPN	VPN is the virtual page number field. This field is compared with the top 20 bits of the virtual address.
PID	PID is the process identifier field. This field is compared with the value of the current process identifier stored in the tlbmisc control register, effectively extending the virtual address. The field size is configurable in the Nios_II Processor parameter editor, and can be between 8 and 14 bits.
G	G is the global flag. When G = 1, the PID is ignored in the TLB lookup.

The TLB data portion determines how to translate a matching virtual address to a physical address.

Table 3-4: TLB Data Portion Contents

Field Name	Description
PFN	PFN is the physical frame number field. This field specifies the upper bits of the physical address. The size of this field depends on the range of physical addresses present in the system. The maximum size is 20 bits.
C	C is the cacheable flag. Determines the default data cacheability of a page. Can be overridden for data accesses using I/O load and store family of Nios II instructions.
R	R is the readable flag. Allows load instructions to read a page.
W	W is the writable flag. Allows store instructions to write a page.
X	X is the executable flag. Allows instruction fetches from a page.

Note: Because there is no "valid bit" in the TLB entry, the operating system software invalidates the TLB by writing unique VPN values from the I/O partition of virtual addresses into each TLB entry.

TLB Lookups

A TLB lookup attempts to convert a virtual address (VADDR) to a physical address (PADDR).

Example 3-1: TLB Lookup Algorithm for Instruction Fetches

```
if (VPN match && (G == 1 || PID match))
   if (X == 1)
      PADDR = concat(PFN, VADDR[11:0])
   else take TLB permission violation exception
else
   if (EH bit of status register == 1)
      take double TLB miss exception
   else
      take fast TLB miss exception
```

Example 3-2: TLB Lookup Algorithm for Data Access Operations

```
if (VPN match && (G == 1 || PID match))
   if ((load && R == 1) || (store && W == 1) || flushda)
      PADDR = concatenate(PFN, VADDR[11:0])
   else
      take TLB permission violation exception
else
   if (EH bit of status register == 1)
      take double TLB miss exception
   else
      take fast TLB miss exception
```

Refer to "Instruction-Related Exceptions" for information about TLB exceptions.

Instruction-Related Exceptions on page 3-51

Memory Protection Unit

The processor provides an MPU for operating systems and runtime environments that desire memory protection but do not require virtual memory management. For information about memory protection with virtual memory management, refer to the Memory Management Unit section.

When present and enabled, the MPU monitors all Nios II instruction fetches and data memory accesses to protect against errant software execution. The MPU is a hardware facility that system software uses to define memory regions and their associated access permissions. The MPU triggers an exception if software attempts to access a memory region in violation of its permissions, allowing you to intervene and handle the exception as appropriate. The precise exception effectively prevents the illegal access to memory.

The MPU extends the processor to support user mode and supervisor mode. Typically, system software runs in supervisor mode and end-user applications run in user mode, although all software can run in supervisor mode if desired. System software defines which MPU regions belong to supervisor mode and which belong to user mode.

MPU protects user application. Therefore for interrupt service, the system must have access to the regions that may cause potential violation because MPU generates exception post access and does not prevent access to the memory region in hardware.

Related Information

Memory Management Unit on page 3-2

Memory Regions

The MPU contains up to 32 instruction regions and 32 data regions. Each region is defined by the following attributes:

- Base address
- Region type
- Region index
- Region size or upper address limit
- Access permissions
- Default cacheability (data regions only)

Base Address

The base address specifies the lowest address of the region. The base address is aligned on a region-sized boundary. For example, a 4-KB region must have a base address that is a multiple of 4 KB. If the base address is not properly aligned, the behavior is undefined.

Region Type

Each region is identified as either an instruction region or a data region.

Region Index

Each region has an index ranging from zero to the number of regions of its region type minus one. Index zero has the highest priority.

Region Size or Upper Address Limit

A generation-time option controls whether the amount of memory in the region is defined by size or upper address limit. The size is an integer power of two bytes. The limit is the highest address of the region plus one. The minimum supported region size is 64 bytes but can be configured for larger minimum sizes to save logic resources. The maximum supported region size equals the Nios II address space (a function of the address ranges of slaves connected to the Nios II masters). Any access outside of the Nios II address space is considered not to match any region and triggers an MPU region violation exception.

A generation-time option controls whether the amount of memory in the region is defined by size or upper address limit. The size is an integer power of two bytes. The limit is the highest address of the region plus one. The minimum supported region size is 256 bytes but can be configured for larger minimum sizes to save logic resources. The maximum supported region size equals the Nios II address space (a function of the address ranges of slaves connected to the Nios II masters). Any access outside of the Nios II address space is considered not to match any region and triggers an MPU region violation exception.

When regions are defined by size, the size is encoded as a binary mask to facilitate the following MPU region address range matching:

```
(address & region_mask) == region_base_address
```

When regions are defined by limit, the limit is encoded as an unsigned integer to facilitate the following MPU region address range matching:

```
(address >= region_base) && (address < region_limit)
```

The region limit uses a less-than instead of a less-than-or-equal-to comparison because less-than provides a more efficient implementation. The limit is one bit larger than the address so that full address range may be included in a range. Defining the region by limit results in slower and larger address range match logic than defining by size but allows finer granularity in region sizes.

Access Permissions

The access permissions consist of execute permissions for instruction regions and read/write permissions for data regions. Any instruction that performs a memory access that violates the access permissions triggers an exception. Additionally, any instruction that performs a memory access that does not match any region triggers an exception.

Default Cacheability

The default cacheability specifies whether normal load and store instructions access the data cache or bypass the data cache. The default cacheability is only present for data regions. You can override the default cacheability by using the `ldwio` or `stwio` instructions. The bit 31 cache bypass feature is available when the MPU is present.

Refer to the Cache Memory section for more information on cache bypass.

The default cacheability specifies whether normal load and store instructions access the data cache or bypass the data cache. The default cacheability is only present for data regions. You can override the default cacheability by using the `ldwio` or `stwio` instructions. The bit-31 cache and Peripheral Region features are available when the MMU is not present.

Refer to the Cache Memory section for more information on cache bypass and Peripheral Region.

Related Information

Cache Memory on page 3-66

Overlapping Regions

The memory addresses of regions can overlap. Overlapping regions have several uses including placing markers or small holes inside of a larger region. For example, the stack and heap may be located in the same region, growing from opposite ends of the address range. To detect stack/heap overflows, you can define a small region between the stack and heap with no access permissions and assign it a higher priority than the larger region. Any access attempts to the hole region trigger an exception informing system software about the stack/heap overflow.

If regions overlap so that a particular access matches more than one region, the region with the highest priority (lowest index) determines the access permissions and default cacheability.

Enabling the MPU

The MPU is disabled on system reset. System software enables and disables the MPU by writing to a control register. Before enabling the MPU, you must create at least one instruction and one data region, otherwise unexpected results can occur. Refer to the Working with the MPU section for more information.

Related Information

Working with the MPU on page 3-37

Registers

The Nios II register set includes general-purpose registers and control registers. In addition, the Nios II/f core can optionally have shadow register sets. This section discusses each register type.

General-Purpose Registers

The Nios II architecture provides thirty-two 32-bit general-purpose registers, `r0` through `r31`. Some registers have names recognized by the assembler. For example, the `zero` register (`r0`) always returns the value zero, and writing to `zero` has no effect. The `ra` register (`r31`) holds the return address used by procedure calls and is implicitly accessed by the `call`, `callr` and `ret` instructions. C and C++ compilers use a common procedure-call convention, assigning specific meaning to registers `r1` through `r23` and `r26` through `r28`.

Table 3-5: The Nios II General-Purpose Registers

Register	Name	Function	Register	Name	Function
r0	zero	0x00000000	r16		Callee-saved register
r1	at	Assembler temporary	r17		Callee-saved register
r2		Return value	r18		Callee-saved register
r3		Return value	r19		Callee-saved register
r4		Register arguments	r20		Callee-saved register
r5		Register arguments	r21		Callee-saved register
r6		Register arguments	r22		Callee-saved register
r7		Register arguments	r23		Callee-saved register
r8		Caller-saved register	r24	et	Exception temporary
r9		Caller-saved register	r25	bt	Breakpoint temporary
r10		Caller-saved register	r26	gp	Global pointer
r11		Caller-saved register	r27	sp	Stack pointer
r12		Caller-saved register	r28	fp	Frame pointer
r13		Caller-saved register	r29	ea	Exception return address
r14		Caller-saved register	r30	sstatus	Status register
r15		Caller-saved register	r31	ra	Return address

Note: `r25` is used exclusively by the JTAG debug module. It is used as the breakpoint temporary (`bt`) register in the normal register set. In shadow register sets, `r25` is reserved.

Note: `r30` is used as the breakpoint return address (`ba`) in the normal register set, and as the shadow register set status (`sstatus`) in each shadow register set. For details about `sstatus`, refer to The Status Register section.

For more information, refer to the *Application Binary Interface* chapter of the *Processor Reference Handbook*.

Related Information

Application Binary Interface on page 7-1

Control Registers

Control registers report the status and change the behavior of the processor. Control registers are accessed differently than the general-purpose registers. The special instructions `rdctl` and `wrctl` provide the only means to read and write to the control registers and are only available in supervisor mode.

Note: When writing to control registers, all undefined bits must be written as zero.

The architecture supports up to 32 control registers. All non-reserved control registers have names recognized by the assembler.

Table 3-6: Control Register Names and Bits

Register	Name	Register Contents
0	`status`	Refer to The status Register on page 3-13
1	`estatus`	Refer to The estatus Register on page 3-15
2	`bstatus`	Refer to The bstatus Register
3	`ienable`	Internal interrupt-enable bits The ienable Register Available only when the external interrupt controller interface is not present. Otherwise reserved.
4	`ipending`	Pending internal interrupt bits The ipending Register Available only when the external interrupt controller interface is not present. Otherwise reserved.
5	`cpuid`	Unique processor identifier
6	Reserved	Reserved
7	`exception`	Refer to The exception Register
8	`pteaddr`	Refer to The pteaddr Register Available only when the MMU is present. Otherwise reserved.
9	`tlbacc`	Refer to The tlbacc Register Available only when the MMU is present. Otherwise reserved.
10	`tlbmisc`	Refer to The tlbmisc Register Available only when the MMU is present. Otherwise reserved.

Register	Name	Register Contents
11	eccinj	Refer to **The eccinj Register** Available only when ECC is present.
12	badaddr	Refer to **The badaddr Register**
13	config	Refer to **The config Register** on page 3-24 Available only when the MPU or ECC is present. Otherwise reserved.

16–31	Reserved	Reserved

The following sections describe the non-reserved control registers.

The status Register

The value in the status register determines the state of the processor. All status bits are set to predefined values at processor reset. Some bits are exclusively used by and available only to certain features of the processor, such as the MMU, MPU or external interrupt controller (EIC) interface.

Table 3-8: status Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								RSIE	NMI	PRS					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRS						IL						IH	EH	U	PIE

Table 3-9: status Control Register Field Descriptions

Bit	Description	Access	Reset	Available
RSIE	RSIE is the register set interrupt-enable bit. When set to 1, this bit allows the processor to service external interrupts requesting the register set that is currently in use. When set to 0, this bit disallows servicing of such interrupts.	Read/Write	1	EIC interface and shadow register sets only(1)
NMI	NMI is the nonmaskable interrupt mode bit. The processor sets NMI to 1 when it takes a nonmaskable interrupt.	Read	0	EIC interface only(4)
PRS	PRS is the previous register set field. The processor copies the CRS field to the PRS field upon one of the following events: • In a processor with no MMU, on any exception • In a processor with an MMU, on one of the following: Break exception Nonbreak exception when status.EH is zero The processor copies CRS to PRS immediately after copying the status register to estatus, bstatus or sstatus. The number of significant bits in the CRS and PRS fields depends on the number of shadow register sets implemented in the Nios II core. The value of CRS and PRS can range from 0 to n-1, where n is the number of implemented register sets. The processor core implements the number of significant bits needed to represent n-1. Unused high-order bits are always read as 0, and must be written as 0. 1 Ensure that system software writes only valid register set numbers to the PRS field. Processor behavior is undefined with an unimplemented register set number.	Read/Write	0	Shadow register sets only(4)

(1) When this field is unimplemented, the field value always reads as 1, and the processor behaves accordingly.

Bit	Description	Access	Reset	Available
CRS	CRS is the current register set field. CRS indicates which register set is currently in use. Register set 0 is the normal register set, while register sets 1 and higher are shadow register sets. The processor sets CRS to zero on any noninterrupt exception. The number of significant bits in the CRS and PRS fields depends on the number of shadow register sets implemented in the Nios II core. Unused high-order bits are always read as 0, and must be written as 0.	Read(2)	0	Shadow register sets only(4)
IL	IL is the interrupt level field. The IL field controls what level of external maskable interrupts can be serviced. The processor services a maskable interrupt only if its requested interrupt level is greater than IL.	Read/Write	0	EIC interface only(4)
IH	IH is the interrupt handler mode bit. The processor sets IH to one when it takes an external interrupt.	Read/Write	0	EIC interface only(4)
EH(3)	EH is the exception handler mode bit. The processor sets EH to one when an exception occurs (including breaks). Software clears EH to zero when ready to handle exceptions again. EH is used by the MMU to determine whether a TLB miss exception is a fast TLB miss or a double TLB miss. In systems without an MMU, EH is always zero.	Read/Write	0	MMU or ECC only(4)
U(3)	U is the user mode bit. When U = 1, the processor operates in user mode. When U = 0, the processor operates in supervisor mode. In systems without an MMU, U is always zero.	Read/Write	0	MMU or MPU only(4)
PIE	PIE is the processor interrupt-enable bit. When PIE = 0, internal and maskable external interrupts and noninterrupt exceptions are ignored. When PIE = 1, internal and maskable external interrupts can be taken, depending on the status of the interrupt controller. Noninterrupt exceptions are unaffected by PIE.	Read/Write	0	Always

Related Information

External Interrupt Controller Interface on page 3-49

The estatus Register

The estatus register holds a saved copy of the status register during nonbreak exception processing.

(2) The CRS field is read-only. For information about manually changing register sets, refer to the External Interrupt Controller Interface section.
(3) The state where both EH and U are one is illegal and causes undefined results.
(4) When this field is unimplemented, the field value always reads as 0, and the processor behaves accordingly.

Table 3-10: estatus Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								RSIE	NMI	PRS					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRS						IL						IH	EH	U	PIE

All fields in the `estatus` register have read/write access. All fields reset to 0.

When the processor takes an interrupt, if `status.eh` is zero (that is, the MMU is in nonexception mode), the processor copies the contents of the `status` register to `estatus`.

Note: If shadow register sets are implemented, and the interrupt requests a shadow register set, the processor copies status to `sstatus`, not to `estatus`.

For details about the `sstatus` register, refer to The sstatus Register section.

The exception handler can examine `estatus` to determine the pre-exception status of the processor. When returning from an exception, the `eret` instruction restores the pre-exception value of `status`. The instruction restores the pre-exception value by copying either `estatus` or `sstatus` back to `status`, depending on the value of `status.CRS`.

Refer to the Exception Processing section for more information.

Related Information

- **Exception Processing** on page 3-42
- **The sstatus Register** on page 3-34

The bstatus Register

The `bstatus` register holds a saved copy of the `status` register during break exception processing.

Table 3-11: bstatus Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved								RSIE	NMI	PRS					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRS						IL						IH	EH	U	PIE

All fields in the `bstatus` register have read/write access. All fields reset to 0.

The Status Control Register Field Description table describes the details of the fields defined in the `bstatus` register.

When a break occurs, the value of the `status` register is copied into `bstatus`. Using `bstatus`, the debugger can restore the `status` register to the value prior to the break. The `bret` instruction causes the processor to copy `bstatus` back to `status`. Refer to the Processing a Break section for more information.

Related Information

Processing a Break on page 3-48

The ienable Register

The `ienable` register controls the handling of internal hardware interrupts. Each bit of the `ienable` register corresponds to one of the interrupt inputs, `irq0` through `irq31`. A value of one in bit n means that the corresponding `irq`n interrupt is enabled; a bit value of zero means that the corresponding interrupt is disabled. Refer to the Exception Processing section for more information.

Note: When the internal interrupt controller is not implemented, the value of the `ienable` register is always 0.

Related Information

Exception Processing on page 3-42

The ipending Register

The value of the `ipending` register indicates the value of the enabled interrupt signals driven into the processor. A value of one in bit n means that the corresponding `irq` n input is asserted and enabled in the `ienable` register. Writing a value to the `ipending` register has no effect.

Note: The `ipending` register is present only when the internal interrupt controller is implemented.

The cpuid Register

The `cpuid` register holds a constant value that you define in the Processor parameter editor to uniquely identify each processor in a multiprocessor system. In , unique values must be assigned manually. Writing to the `cpuid` register has no effect.

The exception Register

When the extra exception information option is enabled, the Nios II processor provides information useful to system software for exception processing in the `exception` and `badaddr` registers when an exception occurs. When your system contains an MMU or MPU, the extra exception information is always enabled. When no MMU or MPU is present, the Processor parameter editor gives you the option to have the processor provide the extra exception information.

/f Processor provides information useful to system software for exception processing in the exception and badaddr registers when an exception occurs.

Note: The exception register is not available for /e core, therefore you cannot add a MMU or MPU to the processor configuration. For more information, refer to the *Core Implementation Details* chapter of this document.

For information about controlling the extra exception information option, refer to the *Instantiating the Processor* chapter of this document.

Programming Model on page 3-1

The pteaddr Register

The pteaddr register contains the virtual address of the operating system's page table and is only available in systems with an MMU. The pteaddr register layout accelerates fast TLB miss exception handling.

Table 3-15: pteaddr Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PTBASE															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Fields	
VPN	Rsvd

Table 3-16: pteaddr Control Register Field Descriptions

Field	Description	Access	Reset	Available
PTBASE	PTBASE is the base virtual address of the page table.	Read/ Write	0	Only with MMU
VPN	VPN is the virtual page number. VPN can be set by both hardware and software.	Read/ Write	0	Only with MMU

Software writes to the PTBASE field when switching processes. Hardware never writes to the PTBASE field.

Software writes to the VPN field when writing a TLB entry. Hardware writes to the VPN field on a fast TLB miss exception, a TLB permission violation exception, or on a TLB read operation. The VPN field is not written on any exceptions taken when an exception is already active, that is, when `status.EH` is already one.

The tlbacc Register

The `tlbacc` register is used to access TLB entries and is only available in systems with an MMU. The `tlbacc` register holds values that software can write into a TLB entry or has previously read from a TLB entry. The `tlbacc` register provides access to only a portion of a complete TLB entry. `pteaddr.VPN` and `tlbmisc.PID` hold the remaining TLB entry fields.

Table 3-17: tlbacc Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IG							C	R	W	X	G	PFN			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PFN															

Issuing a `wrctl` instruction to the `tlbacc` register writes the `tlbacc` register with the specified value. If `tlbmisc.WE` = 1, the `wrctl` instruction also initiates a TLB write operation, which writes a TLB entry. The TLB entry written is specified by the line portion of `pteaddr.VPN` and the `tlbmisc.WAY` field. The value written is specified by the value written into `tlbacc` along with the values of `pteaddr.VPN` and `tlbmisc.PID`. A TLB write operation also increments `tlbmisc.WAY`, allowing software to quickly modify TLB entries.

Issuing a `rdctl` instruction to the `tlbacc` register returns the value of the `tlbacc` register. The `tlbacc` register is written by hardware when software triggers a TLB read operation (that is, when `wrctl` sets `tlbmisc.RD` to one).

Table 3-18: tlbacc Control Register Field Descriptions

Field	Description	Access	Reset	Available
IG	IG is ignored by hardware and available to hold operating system specific information. Read as zero but can be written as nonzero.	Read/ Write	0	Only with MMU
C	C is the data cacheable flag. When C = 0, data accesses are uncacheable. When C = 1, data accesses are cacheable.	Read/ Write	0	Only with MMU
R	R is the readable flag. When R = 0, load instructions are not allowed to access memory. When R = 1, load instructions are allowed to access memory.	Read/ Write	0	Only with MMU
W	W is the writable flag. When W = 0, store instructions are not allowed to access memory. When W = 1, store instructions are allowed to access memory.	Read/ Write	0	Only with MMU
X	X is the executable flag. When X = 0, instructions are not allowed to execute. When X = 1, instructions are allowed to execute.	Read/ Write	0	Only with MMU
G	G is the global flag. When G = 0, tlbmisc.PID is included in the TLB lookup. When G = 1, tlbmisc.PID is ignored and only the virtual page number is used in the TLB lookup.	Read/ Write	0	Only with MMU
PFN	PFN is the physical frame number field. All unused upper bits must be zero.	Read/ Write	0	Only with MMU

The tlbacc register format is the recommended format for entries in the operating system page table. The IG bits are ignored by the hardware on wrctl to tlbacc and read back as zero on rdctl from tlbacc. The operating system can use the IG bits to hold operating system specific information without having to clear these bits to zero on a TLB write operation.

The tlbmisc Register

The tlbmisc register contains the remaining TLB-related fields and is only available in systems with an MMU.

Table 3-19: tlbmisc Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							EE	WAY				RD	WE	PID	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PID												DBL	BAD	PERM	D

Table 3-20: tlbmisc Control Register Field Descriptions

Field	Description	Access	Reset	Available
EE	If this field is a 1, a software-triggered ECC error (1, 2, or 3 bit error) occurred because software initiated a TLB read operation. Only set this field to 1 if CONFIG.ECCEN is 1.	Read/ Write	0	Only with MMU and EEC
WAY	The WAY field controls the mapping from the VPN to a particular TLB entry. This field size is variable. Unused upper bits must be written as zero.	Read/ Write	0	Only with MMU
RD	RD is the read flag. Setting RD to one triggers a TLB read operation.	Write	0	Only with MMU
WE	WE is the TLB write enable flag. When WE = 1, a write to tlbacc writes through to a TLB entry.	Read/ Write	0	Only with MMU
PID	PID is the process identifier field. This field size is variable. Unused upper bits must be written as zero.	Read/ Write	0	Only with MMU
DBL	DBL is the double TLB miss exception flag.	Read	0	Only with MMU
BAD	BAD is the bad virtual address exception flag.	Read	0	Only with MMU
PERM	PERM is the TLB permission violation exception flag.	Read	0	Only with MMU
D	D is the data access exception flag. When D = 1, the exception is a data access exception. When D = 0, the exception is an instruction access exception.	Read	0	Only with MMU

For DBL, BAD, and PERM fields you can also use exception.CAUSE to determine these exceptions.

The following sections provide more information about the tlbmisc fields.

The RD Flag

System software triggers a TLB read operation by setting tlbmisc.RD (with a wrctl instruction). A TLB read operation loads the following register fields with the contents of a TLB entry:

- The tag portion of pteaddr.VPN
- tlbmisc.PID
- The tlbacc register

The TLB entry to be read is specified by the following values:

- the line portion of pteaddr.VPN
- tlbmisc.WAY

When system software changes the fields that specify the TLB entry, there is no immediate effect on pteaddr.VPN, tlbmisc.PID, or the tlbacc register. The registers retain their previous values until the next TLB read operation is initiated. For example, when the operating system sets pteaddr.VPN to a new value, the contents of tlbacc continues to reflect the previous TLB entry. tlbacc does not contain the new TLB entry until after an explicit TLB read.

The WE Flag

When WE = 1, a write to tlbacc writes the tlbacc register and a TLB entry. When WE = 0, a write to tlbacc only writes the tlbacc register.

Hardware sets the WE flag to one on a TLB permission violation exception, and on a TLB miss exception when status.EH = 0. When a TLB write operation writes the tlbacc register, the write operation also writes to a TLB entry when WE = 1.

The WAY Field

The WAY field controls the mapping from the VPN to a particular TLB entry. WAY specifies the set to be written to in the TLB. The MMU increments WAY when system software performs a TLB write operation. Unused upper bits in WAY must be written as zero.

Note: The number of ways (sets) is configurable in at generation time, up to a maximum of 16.

The PID Field

PID is a unique identifier for the current process that effectively extends the virtual address. The process identifier can be less than 14 bits. Any unused upper bits must be zero.

tlbmisc.PID contains the PID field from a TLB tag. The operating system must set the PID field when switching processes, and before each TLB write operation.

Note: Use of the process identifier is optional. To implement memory management without process identifiers, clear tlbmisc.PID to zero. Without a process identifier, all processes share the same virtual address space.

The MMU sets tlbmisc.PID on a TLB read operation. When the software triggers a TLB read, by setting tlbmisc.RD to one with the wrctl instruction, the PID value read from the TLB has priority over the value written by the wrctl instruction.

The size of the PID field is configured in at system generation, and can be from 8 to 14 bits. If system software defines a process identifier smaller than the PID field, unused upper bits must be written as zero.

The DBL Flag

During a general exception, the processor sets DBL to one when a double TLB miss condition exists. Otherwise, the processor clears DBL to zero.

The DBL flag indicates whether the most recent exception is a double TLB miss condition. When a general exception occurs, the MMU sets DBL to one if a double TLB miss is detected, and clears DBL to zero otherwise.

The BAD Flag

During a general exception, the processor sets BAD to one when a bad virtual address condition exists, and clears BAD to zero otherwise. The following exceptions set the BAD flag to one:

- Supervisor-only instruction address
- Supervisor-only data address
- Misaligned data address
- Misaligned destination address

Refer to Nios II Exceptions (In Decreasing Priority Order) table in the "Exception Overview" section for more information on these exceptions.

Related Information

Exception Overview on page 3-42

The PERM Flag

During a general exception, the processor sets PERM to one for a TLB permission violation exception, and clears PERM to zero otherwise.

The D Flag

The D flag indicates whether the exception is an instruction access exception or a data access exception. During a general exception, the processor sets D to one when the exception is related to a data access, and clears D to zero for all other nonbreak exceptions.

The following exceptions set the D flag to one:

- Fast TLB miss (data)
- Double TLB miss (data)
- TLB permission violation (read or write)
- Misaligned data address
- Supervisor-only data address

The badaddr Register

When the extra exception information option is enabled, the processor provides information useful to system software for exception processing in the exception and badaddr registers when an exception occurs. When your system contains an MMU or MPU, the extra exception information is always enabled. When no MMU or MPU is present, the Processor parameter editor gives you the option to have the processor provide the extra exception information.

/f processor provides information useful to system software for exception processing in the exception and badaddr registers when an exception occurs.

Note: The exception register is not available for /e core, therefore you cannot add a MMU or MPU to the processor configuration. For more information, refer to the *Core Implementation Details* chapter of this document.

For information about controlling the extra exception information option, refer to the *Instantiating the Processor* chapter of this document.

When the option for extra exception information is enabled and a processor exception occurs, the badaddr register contains the byte instruction or data address associated with certain exceptions at the time the exception occurred. The Exceptions Table lists which exceptions write the badaddr register along with the value written.

When an exception occurs in /f processor, the badaddr register contains the byte instruction or data address associated with certain exceptions at the time the exception occurred. The Exceptions Table lists which exceptions write the badaddr register along with the value written.

Table 3-21: badaddr Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BADDR															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BADDR															

Table 3-22: badaddr Control Register Field Descriptions

Field	Description	Access	Reset	Available
BADDR	BADDR contains the byte instruction address or data address associated with an exception when certain exceptions occur. The Address column of the Exceptions Table lists which exceptions write the BADDR field.	Read	0	Only with extra exception information

Table 3-23: badaddr Control Register Field Descriptions

Field	Description	Access	Reset	Available
BADDR	BADDR contains the byte instruction address or data address associated with an exception when certain exceptions occur. The Address column of the Exceptions Table lists which exceptions write the BADDR field.	Read	0	Only with /f

The BADDR field allows up to a 32-bit instruction address or data address. If an MMU or MPU is present, the BADDR field is 32 bits because MMU and MPU instruction and data addresses are always full 32-bit values. When an MMU is present, the BADDR field contains the virtual address.

If there is no MMU or MPU and the Nios II address space is less than 32 bits, unused high-order bits are written and read as zero. If there is no MMU, bit 31 of a data address (used to bypass the data cache) is always zero in the BADDR field.

The config Register

The `config` register configures Nios II runtime behaviors that do not need to be preserved during exception processing (in contrast to the information in the `status` register).

Table 3-24: config Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												ECCEXE	ECCEN	ANI	PE

Table 3-25: config Control Register Field Descriptions

Field	Description	Access	Reset	Available
ANI	ANI is the automatic nested interrupt mode bit. If ANI is set to zero, the processor clears status.PIE on each interrupt, disabling fast nested interrupts. If ANI is set to one, the processor keeps status.PIE set to one at the time of an interrupt, enabling fast nested interrupts. If the EIC interface and shadow register sets are not implemented in the Nios II core, ANI always reads as zero, disabling fast nested interrupts.	Read/Write	0	Only with the EIC interface and shadow register sets
ECCEXE	ECCEX is the ECC error exception enable bit. When ECCEXE = 1, the processor generates ECC error exceptions.	Read/Write	0	Only with ECC
ECCEN	ECCEN is the ECC enable bit. When ECCEN = 0, the processor ignores all ECC errors. When ECCEN = 1, the processor recovers all recoverable ECC errors.	Read/Write	0	Only with ECC
PE	PE is the memory protection enable bit. When PE =1, the MPU is enabled. When PE = 0, the MPU is disabled. In systems without an MPU, PE is always zero.	Read/Write	0	Only with MPU

The mpubase Register

The mpubase register works in conjunction with the mpuacc register to set and retrieve MPU region information and is only available in systems with an MPU.

Table 3-26: mpubase Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	BASE(7)														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BASE(7)										INDEX(5)					D

Table 3-27: mpubase Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BASE(7)															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BASE(7)								0		INDEX(6)					D

(5) This field size is variable. Unused upper bits must be written as zero.

(6) This field size is variable. Unused upper bits must be written as zero.

Table 3-28: mpubase Control Register Field Descriptions

Field	Description	Access	Reset	Available
BASE	BASE is the base memory address of the region identified by the INDEX and D fields.	Read/ Write	0	Only with MPU
INDEX	INDEX is the region index number.	Read/ Write	0	Only with MPU
D	D is the region access bit. When D =1, INDEX refers to a data region. When D = 0, INDEX refers to an instruction region.	Read/ Write	0	Only with MPU

The BASE field specifies the base address of an MPU region. The 24-bit BASE field corresponds to bits 8 through 31 of the base address, making the base address always a multiple of 256 bytes. If the minimum region size (set in at generation time) is larger than 256 bytes, unused low-order bits of the BASE field must be written as zero and are read as zero. For example, if the minimum region size is 1024 bytes, the two least-significant bits of the BASE field (bits 8 through 9 of the mpubase register) must be zero. Similarly, if the Nios II address space is less than 31 bits, unused high-order bits must also be written as zero and are read as zero.

The INDEX and D fields specify the region information to access when an MPU region read or write operation is performed. The D field specifies whether the region is a data region or an instruction region. The INDEX field specifies which of the 32 data or instruction regions to access. If there are fewer than 32 instruction or 32 data regions, unused high-order bits must be written as zero and are read as zero.

Refer to the MPU Region Read and Write Operations section for more information on MPU region read and write operations.

Related Information

MPU Region Read and Write Operations on page 3-37

The mpuacc Register

The mpuacc register works in conjunction with the mpubase register to set and retrieve MPU region information and is only available in systems with an MPU. The mpuacc register consists of attributes that can be set or have been retrieved which define the MPU region. The mpuacc register only holds a portion of the attributes that define an MPU region. The remaining portion of the MPU region definition is held by the BASE field of the mpubase register.

A generation-time option controls whether the mpuacc register contains a MASK or LIMIT field.

Table 3-29: mpuacc Control Register Fields for MASK Variation

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[8]															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

(7) This field size is variable. Unused upper bits and unused lower bits must be written as zero.

LIMIT(8)									C	PERM				RD	WR

Table 3-31: mpuacc Control Register Field Descriptions

Field	Description	Access	Reset	Available
MASK	MASK specifies the size of the region.	Read/ Write	0	Only with MPU
LIMIT	LIMIT specifies the upper address limit of the region.	Read/ Write	0	Only with MPU
C	C is the data cacheable flag. C only applies to MPU data regions and determines the default cacheability of a data region. When C = 0, the data region is uncacheable. When C = 1, the data region is cacheable.	Read/ Write	0	Only with MPU
PERM	PERM specifies the access permissions for the region.	Read/ Write	0	Only with MPU
RD	RD is the read region flag. When RD = 1, wrctl instructions to the mpuacc register perform a read operation.	Write	0	Only with MPU
WR	WR is the write region flag. When WR = 1, wrctl instructions to the mpuacc register perform a write operation.	Write	0	Only with MPU

The MASK and LIMIT fields are mutually exclusive. Refer to **Table 3-29** and **Table 3-30**.

Table 3-32: mpuacc Control Register Fields for MASK Variation

Bit Fields

Table 3-34: mpuacc Control Register Field Descriptions

Field	Description	Access	Reset	Available
MASK	MASK specifies the size of the region.	Read/ Write	0	Only with MPU
LIMIT	LIMIT specifies the upper address limit of the region.	Read/ Write	0	Only with MPU
MT	(MT) Memory Type: • 0 = peripheral (non-cacheable, non-write bufferable) • 1 = normal (cacheable, write bufferable) • 2 = device (non-cacheable, write bufferable) • 3 = reserved	Read/ Write	0	Only with MPU
PERM	PERM specifies the access permissions for the region.	Read/ Write	0	Only with MPU
RD	RD is the read region flag. When RD = 1, wrctl instructions to the mpuacc register perform a read operation.	Write	0	Only with MPU
WR	WR is the write region flag. When WR = 1, wrctl instructions to the mpuacc register perform a write operation.	Write	0	Only with MPU

The MASK and LIMIT fields are mutually exclusive. Refer to **Table 3-32** and **Table 3-33**.

Related Information

- **The LIMIT Field** on page 3-30
- **The MASK Field** on page 3-28

The MASK Field

When the amount of memory reserved for a region is defined by size, the MASK field specifies the size of the memory region. The MASK field is the same number of bits as the BASE field of the mpubase register.

Note: Unused high-order or low-order bits must be written as zero and are read as zero.

[8] This field size is variable. Unused upper bits and unused lower bits must be written as zero.

MASK Region Size Encodings Table lists the MASK field encodings for all possible region sizes in a full 31-bit byte address space.

Table 3-35: MASK Region Size Encodings

MASK Encoding	Region Size
0x1FFFFFF	64 bytes
0x1FFFFFE	128 bytes
0x1FFFFFC	256 bytes
0x1FFFFF8	512 bytes
0x1FFFFF0	1 KB
0x1FFFFE0	2 KB
0x1FFFFC0	4 KB
0x1FFFF80	8 KB
0x1FFFF00	16 KB
0x1FFFE00	32 KB
0x1FFFC00	64 KB
0x1FFF800	128 KB
0x1FFF000	256 KB
0x1FFE000	512 KB
0x1FFC000	1 MB
0x1FF8000	2 MB
0x1FF0000	4 MB
0x1FE0000	8 MB
0x1FC0000	16 MB
0x1F80000	32 MB
0x1F00000	64 MB
0x1E00000	128 MB
0x1C00000	256 MB
0x1800000	512 MB
0x1000000	1 GB
0x0000000	2 GB

Table 3-36: MASK Region Size Encodings

MASK Encoding	Region Size
0xFFFFFF	256 bytes

MASK Encoding	Region Size
0xFFFFFE	512 bytes
0xFFFFFC	1 KB
0xFFFFF8	2 KB
0xFFFFF0	4 KB
0xFFFFE0	8 KB
0xFFFFC0	16 KB
0xFFFF80	32 KB
0xFFFF00	64 KB
0xFFFE00	128 KB
0xFFFC00	256 KB
0xFFF800	512 KB
0xFFF000	1 MB
0xFFE000	2 MB
0xFFC000	4 MB
0xFF8000	8 MB
0xFF0000	16 MB
0xFE0000	32 MB
0xFC0000	64 MB
0xF80000	128 MB
0xF00000	256 MB
0xE00000	512 MB
0xC00000	1 GB
0x800000	2 GB
0x000000	4 GB

The MASK field contains the following value, where region_size is in bytes:

```
MASK = 0x1FFFFFF << log2(region_size >> 6)
```

The MASK field contains the following value, where region_size is in bytes:

```
MASK = 0xFFFFFF << log2(region_size >> 8)
```

The LIMIT Field

When the amount of memory reserved for a region is defined by an upper address limit, the LIMIT field specifies the upper address of the memory region plus one. For example, to achieve a memory range for byte addresses 0x4000 to 0x4fff with a 256 byte minimum region size, the BASE field of the mpubase register is set to 0x40 (0x4000 >> 8) and the LIMIT field is set to 0x50 (0x5000 >> 8). Because the LIMIT

field is one more bit than the number of bits of the BASE field of the mpubase register, bit 31 of the mpuacc register is available to the LIMIT field.

The C Flag

The C flag determines the default data cacheability of an MPU region. The C flag only applies to data regions. For instruction regions, the C bit must be written with 0 and is always read as 0.

When data cacheability is enabled on a data region, a data access to that region can be cached, if a data cache is present in the system. You can override the default cacheability and force an address to noncacheable with an ldwio or stwio instruction.

Note: The bit 31 cache bypass feature is supported when the MPU is present. Refer to the Cache memory section for more information on cache bypass.

Related Information

Cache Memory on page 3-66

The MT Flag

The MT flag determines the default memory type of an MPU data region. . The MT flag only applies to data regions. For instruction regions, the MT bit must be written with 0 for instruction regions and is always read as 0.

When data cacheability is enabled on a data region, a data access to that region can be cached, if a data cache is present in the system. You can override the default cacheability and force an address to noncacheable with an ldwio or stwio instruction. The encoding of the MT field is setup to be backwards-compatible with the Classic core MPU where bit 5 of MPUACC contains the cacheable bit (0 = non-cacheable, 1 = cacheable) and bit 6 is zero.

Note: The bit 31 cache bypass feature is supported when the MPU is present. Refer to the Cache memory section for more information on cache bypass.

Note: The bit 31 cache bypass and peripheral region features are supported when the MPU is present. Refer to the Cache memory section for more information on cache bypass.

The PERM Field

The PERM field specifies the allowed access permissions.

Table 3-37: Instruction Region Permission Values

Value	Supervisor Permissions	User Permissions
0	None	None
1	Execute	None
2	Execute	Execute

Table 3-38: Data Region Permission Values

Value	Supervisor Permissions	User Permissions
0	None	None
1	Read	None
2	Read	Read

Value	Supervisor Permissions	User Permissions
4	Read/Write	None
5	Read/Write	Read
6	Read/Write	Read/Write

Note: Unlisted table values are reserved and must not be used. If you use reserved values, the resulting behavior is undefined.

The RD Flag

Setting the RD flag signifies that an MPU region read operation should be performed when a `wrctl` instruction is issued to the `mpuacc` register. Refer to the MPU Region Read and Write Operations section for more information. The RD flag always returns 0 when read by a `rdctl` instruction.

Related Information

MPU Region Read and Write Operations on page 3-37

The WR Flag

Setting the WR flag signifies that an MPU region write operation should be performed when a `wrctl` instruction is issued to the `mpuacc` register. Refer to the MPU Region Read and Write Operations section for more information. The WR flag always returns 0 when read by a `rdctl` instruction.

Note: Setting both the RD and WR flags to one results in undefined behavior.

Related Information

MPU Region Read and Write Operations on page 3-37

The eccinj Register

The `eccinj` register injects 1 and 2 bit errors to the processor's internal RAM blocks that support ECC. Injecting errors allows the software to test the ECC error exception handling code. The error(s) are injected in the data bits, not the parity bits. The `eccinj` register is only available when ECC is present.

Table 3-39: eccinj Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				TLB		Reserved				ICDAT		ICTAG		RF	

Software writes 0x1 to inject a 1 bit ECC error or 0x2 to inject a 2-bit ECC error to the RAM field. Hardware sets the value of the inject field to 0x0 after the error injection has occurred.

Table 3-40: eccinj Control Register Field Descriptions

Field	Description	Access	Reset	Available
RF	Inject an ECC error in the register file's RAM.	Read/ Write	0	Only with ECC
ICTAG	Inject an ECC error in the instruction cache Tag RAM.	Read/ Write	0	Only with ECC
ICDAT	Inject an ECC error in the instruction cache data RAM.	Read/ Write	0	Only with ECC
TLB	Inject an ECC error in the MMU TLB RAM. Errors are injected in the tag portion of the VPN field.	Read/ Write	0	Only with ECC

Refer to "Working with ECC" for more information about when errors are injected.

Table 3-41: eccinj Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved										DC WB		DTCM 3		DTCM 2	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DTCM 1		DTCM 0		TLB		DC DAT		DC TAG		ICDAT		ICTAG		RF	

Software writes 0x1 to inject a 1 bit ECC error or 0x2 to inject a 2-bit ECC error to the RAM field. Hardware sets the value of the inject field to 0x0 after the error injection has occurred.

Table 3-42: eccinj Control Register Field Descriptions

Field	Description	Access	Reset	Available
RF	Inject an ECC error in the register file's RAM.	Read/ Write	0	Only with ECC
ICTAG	Inject an ECC error in the instruction cache Tag RAM.	Read/ Write	0	Only with ECC
ICDAT	Inject an ECC error in the instruction cache data RAM.	Read/ Write	0	Only with ECC
DCTAG	Inject ECC error in data cache tag RAM.	Read/ Write	0	
DCDAT	Inject an ECC error in the data cache data RAM. Injection occurs on next store instruction that writes the data cache or the next line fill.	Read/ Write	0	
TLB	Inject an ECC error in the MMU TLB RAM. Errors are injected in the tag portion of the VPN field.	Read/ Write	0	Only with ECC
DTCM0	Inject ECC error in DTCM0. Injection occurs on next store instruction that writes this DTCM.	Read/ Write	0	

Field	Description	Access	Reset	Available
DTCM1	Inject ECC error in DTCM1. Injection occurs on next store instruction that writes this DTCM.	Read/ Write	0	
DTCM2	Inject ECC error in DTCM2. Injection occurs on next store instruction that writes this DTCM.	Read/ Write	0	
DTCM3	Inject ECC error in DTCM3. Injection occurs on next store instruction that writes this DTCM.	Read/ Write	0	
DC WB	Inject ECC error in data cache victim line buffer RAM. Injection occurs on the first word written into the victim buffer RAM when a dirty line is being written back.	Read/ Write	0	

Refer to "Working with ECC" for more information about when errors are injected.

Related Information

Working with ECC on page 3-38

Shadow Register Sets

The processor can optionally have one or more shadow register sets. A shadow register set is a complete alternate set of Nios II general-purpose registers, which can be used to maintain a separate runtime context for an interrupt service routine (ISR).

When shadow register sets are implemented, `status.CRS` indicates the register set currently in use. A Nios II core can have up to 63 shadow register sets. If n is the configured number of shadow register sets, the shadow register sets are numbered from 1 to n. Register set 0 is the normal register set.

A shadow register set behaves precisely the same as the normal register set. The register set currently in use can only be determined by examining `status.CRS`.

Note: When shadow register sets and the EIC interface are implemented on the Nios II core, you must ensure that your software is built with the Nios II EDS version 9.0 or later. Earlier versions have an implementation of the `eret` instruction that is incompatible with shadow register sets.

Shadow register sets are typically used in conjunction with the EIC interface. This combination can substantially reduce interrupt latency.

For details of EIC interface usage, refer to the Exception Processing section.

System software can read from and write to any shadow register set by setting `status.PRS` and using the `rdprs` and `wrprs` instructions.

For details of the `rdprs` and `wrprs` instructions, refer to the *Instruction Set Reference* chapter of the *Nios II Processor Reference Handbook.*

The sstatus Register

The value in the `sstatus` register preserves the state of the processor during external interrupt handling. The value of `sstatus` is undefined at processor reset. Some bits are exclusively used by and available only to certain features of the processor.

The sstatus register is physically stored in general-purpose register r30 in each shadow register set. The normal register set does not have an sstatus register, but each shadow register set has a separate sstatus register.

Table 3-43: sstatus Control Register Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRS	Reserved							RSIE	NMI	PRS					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRS						IL						IH	EH	U	PIE

Table 3-44: sstatus Control Register Field Descriptions

Bit	Description	Access	Reset	Available
SRS[9]	SRS is the switched register set bit. The processor sets SRS to 1 when an external interrupt occurs, if the interrupt required the processor to switch to a different register set.	Read/Write	Undefined	EIC interface and shadow register sets only
RSIE	RSIE is the register set interrupt-enable bit. When set to 1, this bit allows the processor to service external interrupts requesting the register set that is currently in use. When set to 0, this bit disallows servicing of such interrupts.	Read/Write	Undefined	(10)
NMI	NMI is the nonmaskable interrupt mode bit. The processor sets NMI to 1 when it takes a nonmaskable interrupt.	Read/Write	Undefined	(10)
PRS	(10)	Read/Write	Undefined	(10)
CRS	(10)	Read/Write	Undefined	(10)
IL	(10)	Read/Write	Undefined	(10)
IH	(10)	Read/Write	Undefined	(10)
EH	(10)	Read/Write	Undefined	(10)
U	(10)	Read/Write	Undefined	(10)
PIE	(10)	Read/Write	Undefined	(10)

(9) If the EIC interface and shadow register sets are not present, SRS always reads as 0, and the processor behaves accordingly.
(10) Refer to the status Control Register Field Descriptions Table

The sstatus register is present in the Nios II core if both the EIC interface and shadow register sets are implemented. There is one copy of sstatus for each shadow register set.

When the processor takes an interrupt, if a shadow register set is requested (RRS = 0) and the MMU is not in exception handler mode (status.EH = 0), the processor copies status to sstatus.

For details about RRS, refer to "Requested Register Set".

For details about status.EH, refer to the Processor Status After Taking Exceptions Table.

Changing Register Sets

Modifying status.CRS immediately switches the processor to another register set. However, software cannot write to status.CRS directly. To modify status.CRS, insert the desired value into the saved copy of the status register, and then execute the eret instruction, as follows:

- If the processor is currently running in the normal register set, insert the new register set number in estatus.CRS, and execute eret.
- If the processor is currently running in a shadow register set, insert the new register set number in sstatus.CRS, and execute eret.

Before executing eret to change the register set, system software must set individual external interrupt masks correctly to ensure that registers in the shadow register set cannot be corrupted. If an interrupt is assigned to the register set, system software must ensure that one of the following conditions is true:

- The ISR is written to preserve register contents.
- The individual interrupt is disabled. The method for disabling an individual external interrupt is specific to the EIC implementation.

Stacks and Shadow Register Sets

Depending on system requirements, the system software can create a dedicated stack for each register set, or share a stack among several register sets. If a stack is shared, the system software must copy the stack pointer each time the register set changes. Use the rdprs instruction to copy the stack register between the current register set and another register set.

Initialization with Shadow Register Sets

At initialization, system software must carry out the following tasks to ensure correct software functioning with shadow register sets:

- After the gp register is initialized in the normal register set, copy it to all shadow register sets, to ensure that all code can correctly address the small data sections.
- Copy the zero register from the normal register set to all shadow register sets, using the wrprs instruction.

Working with the MPU

This section provides a basic overview of MPU initialization and the MPU region read and write operations.

MPU Region Read and Write Operations

MPU region read and write operations are operations that access MPU region attributes through the mpubase and mpuacc control registers. The mpubase.BASE, mpuacc.MASK, mpuacc.LIMIT, mpuacc.MT, and mpuacc.PERM fields comprise the MPU region attributes.

MPU region read operations retrieve the current values for the attributes of a region. Each MPU region read operation consists of the following actions:

- Execute a wrctl instruction to the mpubase register with the mpubase.INDEX and mpubase.D fields set to identify the MPU region.
- Execute a wrctl instruction to the mpuacc register with the mpuacc.RD field set to one and the mpuacc.WR field cleared to zero. This action loads the mpubase and mpuacc register values.
- Execute a rdctl instruction to the mpubase register to read the loaded the mpubase register value.
- Execute a rdctl instruction to the mpuacc register to read the loaded the mpuacc register value.

The MPU region read operation retrieves mpubase.BASE, mpuacc.MASK or mpuacc.LIMIT, mpuacc.MT, and mpuacc.PERM values for the MPU region.

Note: Values for the mpubase register are not actually retrieved until the wrctl instruction to the mpuacc register is performed.

MPU region write operations set new values for the attributes of a region. Each MPU region write operation consists of the following actions:

- Execute a wrctl instruction to the mpubase register with the mpubase.INDEX and mpubase.D fields set to identify the MPU region.
- Execute a wrctl instruction to the mpuacc register with the mpuacc.WR field set to one and the mpuacc.RD field cleared to zero.

The MPU region write operation sets the values for mpubase.BASE, mpuacc.MASK or mpuacc.LIMIT, mpuacc.MT, and mpuacc.PERM as the new attributes for the MPU region.

Normally, a wrctl instruction flushes the pipeline to guarantee that any side effects of writing control registers take effect immediately after the wrctl instruction completes execution. However, wrctl instructions to the mpubase and mpuacc control registers do not automatically flush the pipeline. Instead, system software is responsible for flushing the pipeline as needed (either by using a flushp instruction or a wrctl instruction to a register that does flush the pipeline). Because a context switch typically requires reprogramming the MPU regions for the new thread, flushing the pipeline on each wrctl instruction would create unnecessary overhead.

MPU Initialization

Your system software must provide a data structure that contains the region information described in the "Memory Regions" section of this chapter for each active thread. The data structure ideally contains two 32-bit values that correspond to the mpubase and mpuacc register formats.

The MPU is disabled on system reset. Before enabling the MPU, FPGA recommends initializing all MPU regions. Enable desired instruction and data regions by writing each region's attributes to the mpubase and mpuacc registers as described in the "MPU Region Read and Write Operations" section of this chapter. You

must also disable unused regions. When using region size, clear `mpuacc.MASK` to zero. When using limit, set the `mpubase.BASE` to a nonzero value and clear `mpuacc.LIMIT` to zero.

Note: You must enable at least one instruction and one data region, otherwise unpredictable behavior might occur.

To perform a context switch, use a `wrctl` to write a zero to the `PE` field of the `config` register to disable the MPU, define all MPU regions from the new thread's data structure, and then use another `wrctl` to write a one to `config.PE` to enable the MPU.

Define each region using the pair of `wrctl` instructions described in the "MPU Region Read and Write Operations" section of this chapter. Repeat this dual `wrctl` instruction sequence until all desired regions are defined.

Debugger Access

The debugger can access all MPU-related control registers using the normal `wrctl` and `rdctl` instructions. During debugging, the Nios II ignores the MPU, effectively temporarily disabling it.

Working with ECC

Enabling ECC

The ECC is disabled on system reset. Before enabling the ECC, initialize the RAM blocks to avoid spurious ECC errors.

The processor executes the `INITI` instruction on each cache line, which initializes the instruction cache RAM. The RAM does not require special initialization because any detected ECC errors are ignored if the line is invalid; the line is invalid after `INITI` instructions initialize the tag RAM.

processor instructions that write to every register (except register 0) initialize the register file RAM blocks. If shadow register sets are present, this step is performed for all registers in the shadow register set using the `WRPRS` instruction.

processor instructions that write every TLB RAM location initialize the MMU TLB RAM. This RAM does not require special initialization.

Disabling ECC

Disable ECC in software by writing 0 to `CONFIG.ECCEN`. Software can re-enable ECC without reinitializing the ECC-protected RAMs because the ECC parity bits are written to the RAM blocks even if ECC is disabled.

Handling ECC Errors

ECC error exceptions occur when unrecoverable ECC errors are detected. The software's ability to recover from the ECC error depends on the nature of the error.

Typically, software can recover from an unrecoverable MMU TLB ECC error (2 bit error) because the TLB is a software-managed cache of the operating system page tables stored in the main memory (e.g.,

SDRAM). Software can invalid the TLB entry, return to the instruction that took the ECC error exception, and execute the TLB's mishandled code to load a TLB entry from the page tables.

In general, software cannot recover from a register file ECC error (2 bit error) because the correct value of a register is not known. If the exception handler reads a register that has a 2 bit ECC error associated with it, another ECC error occurs and an exception handler loop can occur.

Exception handler loops occur when an ECC error exception occurs in the exception handler before it is ready to handle nested exceptions. To minimize the occurrence or exception handler loops, locate the ECC error exception handler code in normal cacheable memory, ensure that all data accesses are to non-cacheable memory, and minimize register reading.

The ECC error signals (`ecc_event_bus`) provide the `EEH` signal for external logic to detect a possible exception handler loop and reset the processor.

Injecting ECC Errors

This section describes the code sequence for injecting ECC errors for each ECC-protected RAM, assuming the ECC is enabled and interrupts are disabled for the duration of the code sequence.

Instruction Cache Tag RAM

1. Ensure all code up to the JMP instruction is in the same instruction cache line or is located in an ITCM.
2. Use a `FLUSHI` instruction to flush an instruction cache line other than the line containing the executing code.
3. Use a `FLUSHP` instruction to flush the pipeline.
4. Use a `WRCTL` instruction to set `ECCINJ.ICTAG` to `INJS` or `INJD`. This setting causes an ECC error to occur on the start of the next line fill.
5. Use a `JMP` instruction to jump to an instruction address in the flushed line.
6. The ECC error is injected when writing the tag RAM at the start of the line fill.
7. Use a `RDCTL` instruction to ensure that the value of `ECCINJ.ICTAG` is `NOINJ`.
8. The ECC error triggers after the target of the `JMP` instruction.

Instruction Cache Data RAM

1. Ensure all code up to the JMP instruction is in the same instruction cache line or is located in an ITCM.
2. Use a `FLUSHI` instruction to flush an instruction cache line other than the line containing the executing code.
3. Use a `FLUSHP` instruction to flush the pipeline.
4. Use a `WRCTL` instruction to set `ECCINJ.ICDAT` to `INJS` or `INJD`. This setting causes an ECC error to occur on the start of the next line fill.
5. Use a `JMP` instruction to jump to an instruction address in the flushed line.
6. The ECC error is injected when writing the tag RAM at the start of the line fill.
7. Use a `RDCTL` instruction to ensure that the value of `ECCINJ.ICDAT` is `NOINJ`.
8. Execute the target of the `JMP` instruction twice (first to inject the ECC error and second to be triggered by it).

ITCMs

Software running on the cannot directly inject an ECC error in an `ITCM` because the only writes `ITCM`s when correcting ECC errors. To inject an ECC in an `ITCM`, the TCM RAM must also be connected to a

DTCM master. The provided DTCM error injection mechanism (i.e. ECCINJ register) is used to inject an error in the TCM RAM as follows:

1. Use a WRCTL instruction to set ECCINJ so that it injects ECC errors in the DTCM connected to the ITCM.
2. Use a STW instruction to write the DTCM.
3. Use a RDCTL instruction to ensure the value of the ECCINJ field written by the WRCTL is NOINJ.
4. Use a JMP instruction to jump to an instruction address in the ITCM.
5. The ECC error should be triggered on the target of the JMP instruction.

Register File RAM Blocks

1. Use a WRCTL instruction to set ECCINJ.RF to INJS or INJD (as desired).
2. Execute any instruction that writes any register except R0.
3. Use a RDCTL instruction to ensure that the value of ECCINJ.RF is NOINJ.
4. Use an instruction to read the desired register from rA such as OR rd, r0, rx where rx is the register written in the previous step. This action triggers the ECC error.
5. Use an instruction to read the desired register from rB such as OR rd, rx, r0 where rx is the register written in the previous step.

Data Cache Tag RAM

1. Use a LOAD instruction from a data address to get the line in the cache. The line should be clean.
2. Use a WRCTL instruction to set ECCINJ.DCTAG to INJS or INJD.
3. Use a STORE instruction from a data address mapped to that line. The STORE instruction should hit in the data cache and write the tag RAM to set the dirty bit.
4. The ECC error is injected when the tag RAM is written.
5. Use a RDCTL instruction to ensure the value of ECCINJ.DCTAG is NOINJ. Before the RDCTL, use a FLUSHP instruction to avoid the RAW hazard on ECCINJ.
6. Do another LOAD or STORE instruction to the same line.
7. The ECC error should be triggered on this second LOAD/STORE instruction.

Data Cache Data RAM (Clean Line)

1. Use a FLUSHDA instruction to ensure the line isn't in the data cache.
2. Use a LOAD instruction to load a clean data cache line.
3. Use a WRCTL instruction to set ECCINJ.DCDAT field to INJS or INJD.
4. Use a LOAD instruction to an address in the data cache line to inject the error.
5. Use a RDCTL instruction to ensure the values of the field written by the WRCTL to ECCINJ is NOINJ. Before the RDCTL, use a FLUSHP instruction to avoid the RAW hazard on ECCINJ.
6. Use a LOAD instruction from the same address.
7. The ECC error should be triggered on the LOAD instruction.

Data Cache Data RAM (Dirty Line)

1. Use a LOAD instruction to load a data cache line.
2. Use a WRCTL instruction to set ECCINJ.DCDAT field to INJS or INJD (as desired).
3. Use a STORE instruction to an address in the data cache line.
4. Use a RDCTL instruction to ensure the values of the field written by the WRCTL to ECCINJ is NOINJ. Before the RDCTL, use a FLUSHP instruction to avoid the RAW hazard on ECCINJ.
5. Either use a LOAD instruction from the same address or trigger a writeback of the dirty line (e.g. FLUSHDA instruction)
6. The ECC error should be triggered on the LOAD instruction unless it is only detected during the writeback of a dirty line. In the writeback of a dirty line case, the ECC error is triggered an undefined number of instructions later.

Data Cache Victim Line Buffer RAM

1. Use a LOAD instruction to load a data cache line.
2. Use a WRCTL instruction to set ECCINJ.DCWB field to INJS or INJD (as desired).
3. Use a STORE instruction to an address in the data cache line.
4. Use a RDCTL instruction to ensure the values of the field written by the WRCTL to ECCINJ is NOINJ. Before the RDCTL, use a FLUSHP instruction to avoid the RAW hazard on ECCINJ.
5. Either use a LOAD instruction from the same address or trigger a writeback of the dirty line (e.g. FLUSHDA instruction)
6. The ECC error should be triggered on the LOAD instruction unless it is only detected during the writeback of a dirty line. In the writeback of a dirty line case, the ECC error is triggered an undefined number of instructions later.

DTCMs

1. Use a WRCTL instruction to set the ECCINJ.DTCM field to INJS or INJD for the desired DTCM.
2. Use a STW instruction to write an address in the DTCM.
3. Use a RDCTL instruction to ensure the value of the field written by the WRCTL to ECCINJ is NOINJ.
4. Use a LOAD instruction from the same address in the DTCM.
5. The ECC error should be triggered on the LOAD instruction.

MMU TLB RAM

1. Use a WRCTL instruction to set ECCINJ.TLB to INJS or INJD.
2. Use a WRCTL instruction to write a TLB entry. The ECC error is injected at this time and any associated uTLB entry can be flushed.
3. Use a RDCTL instruction to ensure the value of ECCINJ.TLB is NOINJ.
4. Perform an instruction/data access to cause the hardware to read the TLB entry (copied into uTLB) and the ECC decoder should detect the ECC error at this time. Alternatively, initiate a software read of the TLB (by writing TLBMISC.RD to 1).
5. If a software read was initiated, the TLBMISC.EE field should be set to 1 on any instruction after the WRCTL that triggered the software read.
6. If a hardware read was initiated, the ECC error should be triggered on the first instruction after the hardware read.

Exception Processing

Exception processing is the act of responding to an exception, and then returning, if possible, to the pre-exception execution state.

All Nios II exceptions are precise. Precise exceptions enable the system software to re-execute the instruction, if desired, after handling the exception.

Terminology

FPGA and documentation uses the following terminology to discuss exception processing:

- *Exception*—a transfer of control away from a program's normal flow of execution, caused by an event, either internal or external to the processor, which requires immediate attention.
- *Interrupt*—an exception caused by an explicit request signal from an external device; also: hardware interrupt.
- *Interrupt controller*—hardware that interfaces the processor to interrupt request signals from external devices.
- *Internal interrupt controller*—the nonvectored interrupt controller that is integral to the processor. The internal interrupt controller is available in all revisions of the processor.
- *Vectored interrupt controller* (VIC)—an -provided external interrupt controller.
- *Exception (interrupt) latency*—The time elapsed between the event that causes the exception (assertion of an interrupt request) and the execution of the first instruction at the handler address.
- *Exception (interrupt)* response time—The time elapsed between the event that causes the exception (assertion of an interrupt request) and the execution of non-overhead exception code, that is, specific to the exception type (device).
- *Global interrupts*—All maskable exceptions on the processor, including internal interrupts and maskable external interrupts, but not including nonmaskable interrupts.
- *Worst-case latency*—The value of the exception (interrupt) latency, assuming the maximum disabled time or maximum masked time, and assuming that the exception (interrupt) occurs at the beginning of the masked/disabled time.
- *Maximum disabled time*—The maximum amount of continuous time that the system spends with maskable interrupts disabled.
- *Maximum masked time*—The maximum amount of continuous time that the system spends with a single interrupt masked.
- *Shadow register set*—a complete alternate set of Nios II general-purpose registers, which can be used to maintain a separate runtime context for an ISR.

Exception Overview

Each of the Nios II exceptions falls into one of the following categories:

- *Reset exception*—Occurs when the processor is reset. Control is transferred to the reset address you specify in the processor IP core setup parameters.
- *Break exception*—Occurs when the JTAG debug module requests control. Control is transferred to the break address you specify in the processor IP core setup parameters.
- *Interrupt exception*—Occurs when a peripheral device signals a condition requiring service
- *Instruction-related exception*—Occurs when any of several internal conditions occurs, as detailed in the Exceptions Table. Control is transferred to the exception address you specify in the processor IP core setup parameters.

The following table columns specify information for the exceptions:

- *Exception*—Gives the name of the exception.
- *Type*—Specifies the exception type.
- *Available*—Specifies when support for that exception is present.
- *Cause*—Specifies the value of the `CAUSE` field of the `exception` register, for exceptions that write the `exception.CAUSE` field.
- *Address*—Specifies the instruction or data address associated with the exception.
- *Vector*—Specifies which exception vector address the processor passes control to when the exception occurs.

Table 3-45: Nios II Exceptions (In Decreasing Priority Order)

Exception	Type	Available	Cause	Address	Vector
Reset	Reset	Always	0		Reset
Hardware break	Break	Always	—		Break
Processor-only reset request	Reset	Always	1		Reset
Internal interrupt	Interrupt	Internal interrupt controller	2	`ea-4`(12)	General exception
External nonmaskable interrupt	Interrupt	External interrupt controller interface	—	`ea-4`(12)	Requested handler address (13)
External maskable interrupt	Interrupt	External interrupt controller interface	2	`ea-4`(12)	Requested handler address (13)
ECC TLB error (instruction)	Instruction-related	MMU and ECC	18	`ea-4`(12)	General exception
Supervisor-only instruction address (11)	Instruction-related	MMU	9	`ea-4`(12)	General exception
Fast TLB miss (instruction)(11)	Instruction-related	MMU	12	`pteaddr.VPN`, `ea-4`(12)	Fast TLB Miss exception
Double TLB miss (instruction) (11)	Instruction-related	MMU	12	`pteaddr.VPN`, `ea-4`(12)	General exception
TLB permission violation (execute) (11)	Instruction-related	MMU	13	`pteaddr.VPN`, `ea-4`(12)	General exception
ECC register file error	Instruction-related	ECC	20	`ea-4`(12)	General exception
MPU region violation (instruction) (11)	Instruction-related	MPU	16	`ea-4`(12)	General exception

Exception	Type	Available	Cause	Address	Vector
Supervisor-only instruction	Instruction-related	MMU or MPU	10	ea-4(12)	General exception
Trap instruction	Instruction-related	Always	3	ea-4(12)	General exception
Illegal instruction	Instruction-related	Illegal instruction detection on, MMU, or MPU	5	ea-4(12)	General exception
Unimplemented instruction	Instruction-related	Always	4	ea-4(12)	General exception
Break instruction	Instruction-related	Always	—	ba-4(12)	Break
Supervisor-only data address	Instruction-related	MMU	11	badaddr (data address)	General exception
Misaligned data address	Instruction-related	Illegal memory access detection on, MMU, or MPU	6	badaddr (data address)	General exception
Misaligned destination address	Instruction-related	Illegal memory access detection on, MMU, or MPU	7	badaddr (destination address)	General exception
ECC TLB error (data)	Instruction-related	MMU and ECC	18	badaddr (data address)	General exception
Division error	Instruction-related	Division error detection on	8	ea-4(12)	General exception
Fast TLB miss (data)	Instruction-related	MMU	12	pteaddr.VPN, badaddr (data address)	Fast TLB Miss exception
Double TLB miss (data)	Instruction-related	MMU	12	pteaddr.VPN, badaddr (data address)	General exception
TLB permission violation (read)	Instruction-related	MMU	14	pteaddr.VPN, badaddr (data address)	General exception
TLB permission violation (write)	Instruction-related	MMU	15	pteaddr.VPN, badaddr (data address)	General exception

Exception	Type	Available	Cause	Address	Vector
MPU region violation (data)	Instruction-related	MPU	17	badaddr (data address)	General exception

Table 3-46: Nios II Exceptions (In Decreasing Priority Order)

Exception	Type	Available	Cause	Address	Vector
Reset	Reset	Always	0		Reset
Hardware break	Break	Always	—		Break
Processor-only reset request	Reset	Always	1		Reset
ECC Data Cache Writeback Error	Instruction-related	ECC and data cache	22		General exception
Internal interrupt	Interrupt	Internal interrupt controller	2	ea-4 (12)	General exception
External nonmaskable interrupt	Interrupt	External interrupt controller interface	—	ea-4 (12)	Requested handler address (13)
External maskable interrupt	Interrupt	External interrupt controller interface	2	ea-4 (12)	Requested handler address (13)
ECC TLB error (instruction)	Instruction-related	MMU and ECC	18	ea-4 (12)	General exception
Supervisor-only instruction address (11)	Instruction-related	MMU	9	ea-4 (12)	General exception
Fast TLB miss (instruction)(11)	Instruction-related	MMU	12	pteaddr.VPN, ea-4 (12)	Fast TLB Miss exception
Double TLB miss (instruction) (11)	Instruction-related	MMU	12	pteaddr.VPN, ea-4 (12)	General exception
TLB permission violation (execute) (11)	Instruction-related	MMU	13	pteaddr.VPN, ea-4 (12)	General exception
ECC register file error	Instruction-related	ECC	20	ea-4 (12)	General exception
MPU region violation (instruction) (11)	Instruction-related	MPU	16	ea-4 (12)	General exception
Bus Instruction Fetch Error		M Core	23	ea-4 (12)	General exception
ECC Fetch Error (instruction fetch)		ECC and ITCM	19	ea-4 (12)	General exception
ECC Register File Error		ECC	20	ea-4 (12)	General exception

Exception	Type	Available	Cause	Address	Vector
Supervisor-only instruction	Instruction-related	MMU or MPU	10	ea-4(12)	General exception
Trap instruction	Instruction-related	Always	3	ea-4(12)	General exception
Illegal instruction	Instruction-related	Illegal instruction detection on, MMU, or MPU	5	ea-4(12)	General exception
Unimplemented instruction	Instruction-related	Always	4	ea-4(12)	General exception
Break instruction	Instruction-related	Always	—	ba-4(12)	Break
Supervisor-only data address	Instruction-related	MMU	11	badaddr (data address)	General exception
Misaligned data address	Instruction-related	Illegal memory access detection on, MMU, or MPU	6	badaddr (data address)	General exception
Misaligned destination address	Instruction-related	Illegal memory access detection on, MMU, or MPU	7	badaddr (destination address)	General exception

Exception Latency

Exception latency specifies how quickly the system can respond to an exception. Exception latency depends on the type of exception, the software and hardware configuration, and the processor state.

Interrupt Latency

The interrupt controller can mask individual interrupts. Each interrupt can have a different maximum masked time. The worst-case interrupt latency for interrupt i is determined by that interrupt's maximum masked time, or by the maximum disabled time, whichever is greater.

Reset Exceptions

When a processor reset signal is asserted, the processor performs the following steps:

1. Sets `status.RSIE` to 1, and clears all other fields of the `status` register.
2. Invalidates the instruction cache line associated with the reset vector.
3. Begins executing the reset handler, located at the reset vector.

Note: All noninterrupt exception handlers must run in the normal register set.

Clearing the `status.PIE` field disables maskable interrupts. If the MMU or MPU is present, clearing the `status.U` field forces the processor into supervisor mode.

Note: Nonmaskable interrupts (NMIs) are not affected by `status.PIE`, and can be taken while processing a reset exception.

Invalidating the reset cache line guarantees that instruction fetches for reset code comes from uncached memory.

Aside from the instruction cache line associated with the reset vector, the contents of the cache memories are indeterminate after reset. To ensure cache coherency after reset, the reset handler located at the reset vector must immediately initialize the instruction cache. Next, either the reset handler or a subsequent routine should proceed to initialize the data cache.

The reset state is undefined for all other system components, including but not limited to:

- General-purpose registers, except for `zero` (`r0`) in the normal register set, which is permanently zero.
- Control registers, except for `status`. `status.RSIE` is reset to 1, and the remaining fields are reset to 0.
- Instruction and data memory.
- Cache memory, except for the instruction cache line associated with the reset vector.
- Peripherals. Refer to the appropriate peripheral data sheet or specification for reset conditions.
- Custom instruction logic
- Nios II C-to-hardware (C2H) acceleration compiler logic.

(11) It is possible for any instruction fetch to cause this exception.
(12) Refer to the General-Purpose Registers Table for descriptions of the `ea` and `ba` registers.
(13) For a description of the requested handler address, refer to the Requested Handler Address section of this chapter.

For more information refer to the Nios II Custom Instruction User Guide for reset conditions.

Break Exceptions

A break is a transfer of control away from a program's normal flow of execution for the purpose of debugging. Software debugging tools can take control of the processor via the JTAG debug module.

Break processing is the means by which software debugging tools implement debug and diagnostic features, such as breakpoints and watchpoints. Break processing is a type of exception processing, but the break mechanism is independent from general exception processing. A break can occur during exception processing, enabling debug tools to debug exception handlers.

The processor enters the break processing state under either of the following conditions:

- The processor executes the `break` instruction. This is often referred to as a software break.
- The JTAG debug module asserts a hardware break.

Processing a Break

A break causes the processor to take the following steps:

1. Stores the contents of the `status` register to `bstatus`.
2. Clears `status.PIE` to zero, disabling maskable interrupts.

Note: Nonmaskable interrupts (NMIs) are not affected by `status.PIE`, and can be taken while processing a break exception.

1. Writes the address of the instruction following the break to the `ba` register (`r30`) in the normal register set.
2. Clears `status.U` to zero, forcing the processor into supervisor mode, when the system contains an MMU or MPU.
3. Sets `status.EH` to one, indicating the processor is handling an exception, when the system contains an MMU.
4. Copies `status.CRS` to `status.PRS` and then sets `status.CRS` to 0.
5. Transfers execution to the break handler, stored at the break vector specified in the Processor parameter editor.

Note: All noninterrupt exception handlers, including the break handler, must run in the normal register set.

Understanding Register Usage

The `bstatus` control register and general-purpose registers `bt` (`r25`) and `ba` (`r30`) in the normal register set are reserved for debugging. Code is not prevented from writing to these registers, but debug code might overwrite the values. The break handler can use `bt` (`r25`) to help save additional registers.

Returning From a Break

After processing a break, the break handler releases control of the processor by executing a `bret` instruction. The `bret` instruction restores `status` by copying the contents of `bstatus` and returns program execution to the address in the `ba` register (`r30`) in the normal register set. Aside from `bt` and `ba`, all registers are guaranteed to be returned to their pre-break state after returning from the break handler.

Interrupt Exceptions

A peripheral device can request an interrupt by asserting an interrupt request (IRQ) signal. IRQs interface to the processor through an interrupt controller. You can configure the processor with either of the following interrupt controller options:

- The external interrupt controller interface
- The internal interrupt controller

External Interrupt Controller Interface

The Nios II EIC interface enables you to connect the processor to an external interrupt controller component. The EIC can monitor and prioritize IRQ signals, and determine which interrupt to present to the processor. An EIC can be software-configurable.

The processor does not depend on any particular implementation of an EIC. The degree of EIC configurability, and EIC configuration methods, are implementation-specific. This section discusses the EIC interface, and general features of EICs. For usage details, refer to the documentation for the specific EIC in your system.

When an IRQ is asserted, the EIC presents the following information to the processor:

- The requested handler address (RHA)—Refer to the Requested Handler Address section of this chapter
- The requested interrupt level (RIL)—Refer to the Requested Interrupt Level section of this chapter
- The requested register set (RRS)—Refer to Requested Register Set section of this chapter
- Requested nonmaskable interrupt (RNMI) mode—Refer to the Requested NMI Mode section of this chapter

The processor EIC interface connects to a single EIC, but an EIC can support a daisy-chained configuration. In a daisy-chained configuration, multiple EICs can monitor and prioritize interrupts. The EIC directly connected to the processor presents the processor with the highest-priority interrupt from all EICs in the daisy chain.

An EIC component can support an arbitrary level of daisy-chaining, potentially allowing the processor to handle an arbitrary number of prioritized interrupts.

For a typical EIC implementation, refer to the *Vectored Interrupt Controller* chapter in the *Embedded Peripherals IP User Guide*.

Related Information

- **Requested NMI Mode** on page 3-50
- **Requested Register Set** on page 3-50
- **Requested Interrupt Level** on page 3-50

Requested Handler Address

The RHA specifies the address of the handler associated with the interrupt. The availability of an RHA for each interrupt allows the processor to jump directly to the interrupt handler, reducing interrupt latency.

The RHA for each interrupt is typically software-configurable. The method for specifying the RHA is dependent on the specific EIC implementation.

If the processor is implemented with an MMU, the processor treats handler addresses as virtual addresses.

Requested Interrupt Level

The processor uses the RIL to decide when to take a maskable interrupt. The interrupt is taken only when the RIL is greater than `status.IL`.

The RIL is ignored for nonmaskable interrupts.

Requested Register Set

If shadow register sets are implemented on the Nios II core, the EIC specifies a register set when it asserts an interrupt request. When it takes the interrupt, the processor switches to the requested register set. When an interrupt has a dedicated register set, the interrupt handler avoids the overhead of saving registers.

The method of assigning register sets to interrupts depends on the specific EIC implementation. Register set assignments can be software-configurable.

Multiple interrupts can be configured to share a register set. In this case, the interrupt handlers must be written so as to avoid register corruption. For example, one of the following conditions must be true:

- The interrupts cannot pre-empt one another. For example, all interrupts are at the same level.
- Registers are saved in software. For example, each interrupt handler saves its own registers on entry, and restores them on exit.

Typically, the processor is configured so that when it takes an interrupt, other interrupts in the same register set are disabled. If interrupt preemption within a register set is desired, the interrupt handler can re-enable interrupts in its register set.

By default, the processor disables maskable interrupts when it takes an interrupt request. To enable nested interrupts, system software or the ISR itself must re-enable interrupts after the interrupt is taken.

Requested NMI Mode

Any interrupt can be nonmaskable, depending on the configuration of the EIC. An NMI typically signals a critical system event requiring immediate handling, to ensure either system stability or real-time performance.

`status.IL` and RIL are ignored for nonmaskable interrupts.

Shadow Register Sets

Although shadow register sets can be implemented independently of the EIC interface, typically the two features are used together. Combining shadow register sets with an appropriate EIC, you can minimize or eliminate the context switch overhead for critical interrupts.

For the best interrupt performance, assign a dedicated register set to each of the most time-critical interrupts. Less-critical interrupts can share register sets, provided the ISRs are protected from register corruption as noted in the Requested Register Set section of this chapter.

The method for mapping interrupts to register sets is specific to the particular EIC implementation.

Related Information

Requested Register Set on page 3-50

Internal Interrupt Controller

When the internal interrupt controller is implemented, a peripheral device can request a hardware interrupt by asserting one of the processor's 32 interrupt-request inputs, `irq0` through `irq31`. A hardware interrupt is generated if and only if all three of these conditions are true:

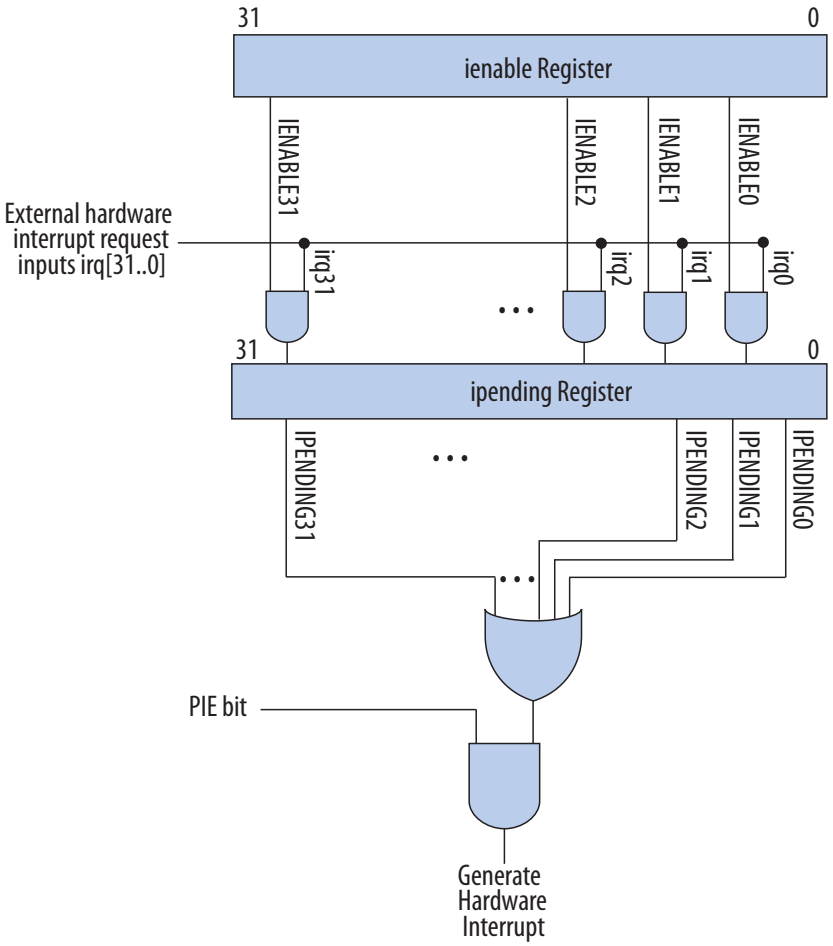
- The PIE bit of the status control register is one.
- An interrupt-request input, irqn, is asserted.
- The corresponding bit n of the ienable control register is one.

Upon hardware interrupt, the processor clears the PIE bit to zero, disabling further interrupts, and performs the other steps outlined in the "Exception Processing Flow" section of this chapter.

The value of the ipending control register shows which interrupt requests (IRQ) are pending. By peripheral design, an IRQ bit is guaranteed to remain asserted until the processor explicitly responds to the peripheral.

Note: Although shadow register sets can be implemented in any Nios II/f processor, the internal interrupt controller does not have features to take advantage of it as external interrupt controllers do.

Figure 3-2: Relationship Between ienable, ipending, PIE and Hardware Interrupts



Related Information

Exception Processing Flow on page 3-56

Instruction-Related Exceptions

Instruction-related exceptions occur during execution of Nios II instructions. When they occur, the processor perform the steps outlined in the "Exception Processing Flow" section of this chapter.

The processor generates the following instruction-related exceptions:

- Trap instruction
- Break instruction
- Unimplemented instruction
- Illegal instruction
- Supervisor-only instruction
- Supervisor-only instruction address
- Supervisor-only data address
- Misaligned data address
- Misaligned destination address
- Division error
- Fast TLB miss
- Double TLB miss
- TLB permission violation
- MPU region violation

Note: All noninterrupt exception handlers must run in the normal register set.

Related Information

Exception Processing Flow on page 3-56

Trap Instruction

When a program issues the `trap` instruction, the processor generates a software trap exception. A program typically issues a software trap when the program requires servicing by the operating system. The general exception handler for the operating system determines the reason for the trap and responds appropriately.

Break Instruction

The break instruction is treated as a break exception. For more information, refer to the "Break Exceptions" section of this chapter.

Related Information

Break Exceptions on page 3-48

Unimplemented Instruction

When the processor issues a valid instruction that is not implemented in hardware, an unimplemented instruction exception is generated. The general exception handler determines which instruction generated the exception. If the instruction is not implemented in hardware, control is passed to an exception routine that might choose to emulate the instruction in software.

For more information, refer to the "Potential Unimplemented Instructions" section of this chapter.

Related Information

Potential Unimplemented Instructions on page 3-74

Illegal Instruction

Illegal instructions are instructions with an undefined opcode or opcode-extension field. The processor can check for illegal instructions and generate an exception when an illegal instruction is encountered. When your system contains an MMU or MPU, illegal instruction checking is always on. When no MMU or MPU is present, you have the option to have the processor check for illegal instructions.

Illegal instructions are instructions with an undefined opcode or opcode-extension field. The processor can check for illegal instructions and generate an exception when an illegal instruction is encountered. Illegal instruction checking is always on regardless of MMU or MPU settings.

For information about controlling this option, refer to the *Instantiating the Processor* chapter of the *Processor Reference Handbook*.

When the processor issues an instruction with an undefined opcode or opcode-extension field, and illegal instruction exception checking is turned on, an illegal instruction exception is generated.

Refer to the OP Encodings and OPX Encodings for R-Type Instructions tables in the *Instruction Set Reference* chapter of the *Processor Reference Handbook* to see the unused opcodes and opcode extensions.

Note: All undefined opcodes are reserved. The processor does occasionally use some undefined encodings internally. Executing one of these undefined opcodes does not trigger an illegal instruction exception.

Refer to the *Nios II Core Implementation Details* chapter of the *Processor Reference Handbook* for information about each specific Nios II core.

Related Information

- **Instruction Set Reference** on page 8-1
- **Programming Model** on page 3-1
- **Core Implementation Details** on page 5-1

Supervisor-Only Instruction

When your system contains an MMU or MPU and the processor is in user mode (`status.U = 1`), executing a supervisor-only instruction results in a supervisor-only instruction exception. The supervisor-only instructions are `initd`, `initi`, `eret`, `bret`, `rdctl`, and `wrctl`.

This exception is implemented only in processors configured to use supervisor mode and user mode. Refer to the "Operating Modes" section of this chapter for more information.

Related Information

Operating Modes on page 3-1

Supervisor-Only Instruction Address

When your system contains an MMU and the processor is in user mode (`status.U = 1`), attempts to access a supervisor-only instruction address result in a supervisor-only instruction address exception. Any instruction fetch can cause this exception. For definitions of supervisor-only address ranges, refer to the Virtual Memory Partitions Table.

This exception is implemented only in processors that include the MMU.

Related Information

Virtual Memory Address Space on page 3-4

Supervisor-Only Data Address

When your system contains an MMU and the processor is in user mode (`status.U = 1`), any attempt to access a supervisor-only data address results in a supervisor-only data address exception. Instructions that can cause a supervisor-only data address exception are all loads, all stores, and `flushda`.

This exception is implemented only in processors that include the MMU.

Misaligned Data Address

The processor can check for misaligned data addresses of load and store instructions and generate an exception when a misaligned data address is encountered. When your system contains an MMU or MPU, misaligned data address checking is always on. When no MMU or MPU is present, you have the option to have the processor check for misaligned data addresses.

For information about controlling this option, refer to the *Instantiating the Processor* chapter of the *Processor Reference Handbook*.

A data address is considered misaligned if the byte address is not a multiple of the width of the load or store instruction data width (four bytes for word, two bytes for half-word). Byte load and store instructions are always aligned so never take a misaligned address exception.

Related Information

Programming Model on page 3-1

Misaligned Destination Address

The processor can check for misaligned destination addresses of the `callr`, `jmp`, `ret`, `eret`, `bret`, and all branch instructions and generate an exception when a misaligned destination address is encountered. When your system contains an MMU or MPU, misaligned destination address checking is always on. When no MMU or MPU is present, you have the option to have the processor check for misaligned destination addresses.

For information about controlling this option, refer to the *Instantiating the Processor* chapter of the *Processor Reference Handbook*.

A destination address is considered misaligned if the target byte address of the instruction is not a multiple of four.

Related Information

Programming Model on page 3-1

Division Error

The processor can check for division errors and generate an exception when a division error is encountered.

The division error exception detects divide instructions that produce a quotient that can't be represented. The two cases are divide by zero and a signed division that divides the largest negative number -2147483648 (0x80000000) by -1 (0xffffffff). Division error detection is only available if divide instructions are supported by hardware.

Related Information

Programming Model on page 3-1

Fast TLB Miss

Fast TLB miss exceptions are implemented only in processors that include the MMU. The MMU has a special exception vector (fast TLB miss), specified with the Processor parameter editor in , specifically to handle TLB miss exceptions quickly. Whenever the processor cannot find a TLB entry matching the VPN (optionally extended by a process identifier), the result is a TLB miss exception. At the time of the exception, the processor first checks `status.EH`. When `status.EH` = 0, no other exception is already in process, so the processor considers the TLB miss a fast TLB miss, sets `status.EH` to one, and transfers control to the fast TLB miss exception handler (rather than to the general exception handler).

There are two kinds of fast TLB miss exceptions:

- Fast TLB miss (instruction)—Any instruction fetch can cause this exception.
- Fast TLB miss (data)—Load, store, `initda`, and `flushda` instructions can cause this exception.

The fast TLB miss exception handler can inspect the `tlbmisc.D` field to determine which kind of fast TLB miss exception occurred.

Double TLB Miss

Double TLB miss exceptions are implemented only in processors that include the MMU. When a TLB miss exception occurs while software is currently processing an exception (that is, when `status.EH` = 1), a double TLB miss exception is generated. Specifically, whenever the processor cannot find a TLB entry matching the VPN (optionally extended by a process identifier) and `status.EH` = 1, the result is a double TLB miss exception. The most common scenario is that a double TLB miss exception occurs during processing of a fast TLB miss exception. The processor preserves register values from the original exception and transfers control to the general exception handler which processes the newly-generated exception.

There are two kinds of double TLB miss exceptions:

- Double TLB miss (instruction)—Any instruction fetch can cause this exception.
- Double TLB miss (data)—Load, store, `initda`, and `flushda` instructions can cause this exception.

The general exception handler can inspect either the `exception.CAUSE` or `tlbmisc.D` field to determine which kind of double TLB miss exception occurred.

TLB Permission Violation

TLB permission violation exceptions are implemented only in processors that include the MMU. When a TLB entry is found matching the VPN (optionally extended by a process identifier), but the permissions do not allow the access to complete, a TLB permission violation exception is generated.

There are three kinds of TLB permission violation exceptions:

- TLB permission violation (execute)—Any instruction fetch can cause this exception.
- TLB permission violation (read)—Any load instruction can cause this exception.
- TLB permission violation (write)—Any store instruction can cause this exception.

The general exception handler can inspect the `exception.CAUSE` field to determine which permissions were violated.

Note: The data cache management instructions (`initd`, `initda`, `flushd`, and `flushda`) ignore the TLB permissions and do not generate TLB permission violation exceptions.

MPU Region Violation

MPU region violation exceptions are implemented only in processors that include the MPU. An MPU region violation exception is generated under any of the following conditions:

- An instruction fetch or data address matched a region but the permissions for that region did not allow the action to complete.
- An instruction fetch or data address did not match any region.

The general exception handler reads the MPU region attributes to determine if the address did not match any region or which permissions were violated.

There are two kinds of MPU region violation exceptions:

- MPU region violation (instruction)—Any instruction fetch can cause this exception.
- MPU region violation (data)—Load, store, `initda`, and `flushda` instructions can cause this exception.

The general exception handler can inspect the `exception.CAUSE` field to determine which kind of MPU region violation exception occurred.

Other Exceptions

The preceding sections describe all of the exception types defined by the Nios II architecture at the time of publishing. However, some processor implementations might generate exceptions that do not fall into the categories listed in the preceding sections. Therefore, a robust exception handler must provide a safe response (such as issuing a warning) in the event that it cannot identify the cause of an exception.

Exception Processing Flow

Except for the break exception (refer to the Processing a Break section of this chapter), this section describes how the processor responds to exceptions, including interrupts and instruction-related exceptions.

Related Information

- **Exception Handling**
  For details about writing programs to take advantage of exception and interrupt handling, refer to the Exception Handling chapter of the Nios II Software Developer's Handbook.
- **Processing a Break** on page 3-48

Processing General Exceptions

The general exception handler is a routine that determines the cause of each exception (including the double TLB miss exception), and then dispatches an exception routine to respond to the exception. The address of the general exception handler, specified with the Processor parameter editor in , is called the exception vector in the Processor parameter editor. At run time this address is fixed, and software cannot modify it. Programmers do not directly access exception vectors, and can write programs without awareness of the address.

Note: If the EIC interface is present, the general exception handler processes only noninterrupt exceptions.

The fast TLB miss exception handler only handles the fast TLB miss exception. It is built for speed to process TLB misses quickly. The fast TLB miss exception handler address, specified with the Processor parameter editor in , is called the fast TLB miss exception vector in the Processor parameter editor.

Exception Flow with the EIC Interface

If the EIC interface is present, interrupt processing differs markedly from noninterrupt exception processing. The EIC interface provides the following information to the processor for each interrupt request:

- RHA—The requested handler address for the interrupt handler assigned to the requested interrupt.
- RRS—The requested register set to be used when the interrupt handler executes. If shadow register sets are not implemented, RRS must always be 0.
- RIL—The requested interrupt level specifies the priority of the interrupt.
- RNMI—The requested NMI flag specifies whether to treat the interrupt as nonmaskable.

  For further information about the RHA, RRS, RIL and RNMI, refer to "The Nios II/f Core" in the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

When the EIC interface presents an interrupt to the processor, the processor uses several criteria, as follows, to determine whether to take the interrupt:

- Nonmaskable interrupts—The processor takes any NMI as long as it is not processing a previous NMI.
- Maskable interrupts—The processor takes a maskable interrupt if maskable interrupts are enabled, and if the requested interrupt level is higher than that of the interrupt currently being processed (if any). However, if shadow register sets are implemented, the processor takes the interrupt only if the interrupt requests a register set different from the current register set, or if the register set interrupt enable flag (`status.RSIE`) is set.

Table 3-47: Conditions Required to Take External Interrupt

RNMI == 1		RNMI == 0					
			status.PIE == 1				
				RIL > status.IL			
				Processor Has Shadow Register Sets			
				RRS == status.CRS		RRS != status.CRS	No Shadow Register Sets
status.NMI == 0	status.NMI == 1	status.PIE == 0	RIL <= status.IL	status.RSIE == 0	status.RSIE == 1		
Yes	No	No	No	No [14]	Yes	Yes	Yes

The processor supports fast nested interrupts with shadow register sets, as described in the "Shadow Register Set" section of this chapter.

Keeping `status.PIE` set allows higher level interrupts to be taken immediate, without requiring the interrupt handler to set `status.PIE` to 1.

The processor disables maskable interrupts when taking an exception, just as it does without shadow register sets. An individual interrupt handler can re-enable interrupts by setting `status.PIE` to 1, if desired.

Related Information

- **Shadow Register Sets** on page 3-50
- **Core Implementation Details** on page 5-1

[14] Nested interrupts using the same register set are allowed only if system software has explicitly permitted them by setting `status.RSIE`. This restriction ensures that such interrupts are taken only if the handler is coded to save the register context.

Exception Flow with the Internal Interrupt Controller

A general exception handler determines which of the pending interrupts has the highest priority, and then transfers control to the appropriate ISR. The ISR stops the interrupt from being visible (either by clearing it at the source or masking it using `ienable`) before returning as well as before re-enabling `PIE`. The ISR also saves `estatus` and `ea` (`r29`) before re-enabling `PIE`.

Interrupts can be re-enabled by writing one to the `PIE` bit, thereby allowing the current ISR to be interrupted. Typically, the exception routine adjusts `ienable` so that IRQs of equal or lower priority are disabled before re-enabling interrupts.

Refer to "Handling Nested Exceptions" for more information.

Related Information

Handling Nested Exceptions on page 3-62

Exceptions and Processor Status

The Processor Status After Taking Exception Table lists all changes to the processor state as a result of nonbreak exception processing actions performed by hardware. For systems with an MMU, `status.EH` indicates whether or not exception processing is already in progress. When `status.EH` = 1, exception processing is already in progress and the states of the exception registers are preserved to retain the original exception states.

Table 3-48: Processor Status After Taking Exception

Processor Status Register or Field	System Status Before Taking Exception							
	External Interrupt Asserted (15)				Internal Interrupt Asserted or Noninterrupt Exception			
	status.EH==1 (30)		status.EH==0		status.EH==1	status.EH==0		
							No TLB Miss	
	RRS==0 (31)	RRS!=0	RRS==0	RRS!=0		TLB Miss (32)	TLB Permission Violation (32)	No TLB Permission Violation
`pteaddr.VPN` (16)	No change					VPN (17)		No change
`status.PRS` (31)	No change		`status.CRS` (31) (33)		No change			
`pc`	RHA				General exception vector (18)	Fast TLB exception vector (19)	General exception vector (31)	
`sstatus` (20)(34)	No change			`status` (33) (21)	No change			
`estatus` (34)	No change		`status` (33)	No change			`status` (33)	
`ea`	No change		return address (22)		No change	return address		

(15) If the processor does not have an EIC interface, external interrupts do not occur.
(16) If the processor does not have an MMU, this register is not implemented.
(17) The VPN of the address triggering the exception
(18) Invokes the general exception handler
(19) Invokes the fast TLB miss exception handler
(20) If the processor does not have shadow register sets, this register is not implemented.
(21) `sstatus.SRS` is set to 1 if RRS is not equal to `status.CRS`.
(22) The address following the instruction being executed when the exception occurs

Processor Status Register or Field	System Status Before Taking Exception							
	External Interrupt Asserted (15)				Internal Interrupt Asserted or Noninterrupt Exception			
	status.EH==1 (30)		status.EH==0		status.EH==1	status.EH==0		
							No TLB Miss	
	RRS==0 (31)	RRS!=0	RRS==0	RRS!=0		TLB Miss (32)	TLB Permission Violation (32)	No TLB Permission Violation
tlbmisc.D (30)	No change					(23)		
tlbmisc.DBL (30)	No change					(24)		
tlbmisc.PERM(30)	No change					(25)		
tlbmisc.BAD (30)	No change					(26)		
status.PIE	No change				0 (27)			
status.EH(30)	No change				1 (28)			
status.IH (36)	1				No change			
status.NMI (36)	RNMI				No change			
status.IL (36)	RIL				No change			
status.RSIE (31)(36)	0				No change			
status.CRS (31)	RRS				No change			
status.U (30)	0 (29)							

(15) If the processor does not have an EIC interface, external interrupts do not occur.
(23) Set to 1 on a data access exception, set to 0 otherwise
(24) Set to 1 on a double TLB miss, set to 0 otherwise
(25) Set to 1 on a TLB permission violation, set to 0 otherwise
(26) Set to 1 on a bad virtual address exception, set to 0 otherwise
(27) Disables exceptions and nonmaskable interrupts
(28) If the MMU is implemented, indicates that the processor is handling an exception.
(29) Puts the processor in supervisor mode.
(30) If the processor does not have an MMU, this field is not implemented. Its value is always 0, and the processor behaves accordingly.
(31) If the processor does not have shadow register sets, this field is not implemented. Its value is always 0, and the processor behaves accordingly.
(32) If the processor does not have an MMU, TLB-related exceptions do not occur.
(33) The pre-exception value
(34) Saves the processor's pre-exception status
(35) If the MMU is implemented, indicates that the processor is handling an exception.
(36) If the processor does not have an EIC interface, this field is not implemented.

Determining the Cause of Interrupt and Instruction-Related Exceptions

The general exception handler must determine the cause of each exception and then transfer control to an appropriate exception routine.

With Extra Exception Information

When you have included the extra exception information in your Nios II system, the CAUSE field of the exception register contains a code for the highest-priority exception occurring at the time and the BADDR field of the badaddr register contains the byte instruction address or data address for certain exceptions.

Refer to the Exceptions table for more information in the Exception Overview section.

Note: External interrupts do not set exception.CAUSE.

To determine the cause of an exception, simply read the cause of the exception from exception.CAUSE and then transfer control to the appropriate exception routine.

Note: Extra exception information is always enabled in systems containing an MMU or MPU.

Related Information

- **The exception Register** on page 3-17
- **The badaddr Register** on page 3-23
- **Exception Overview** on page 3-42

Without Extra Exception Information

When you have not included the extra exception information in your system, your exception handler must determine the cause of exception itself. For this reason, recommends always enabling the extra exception information.

When the extra exception information is not available, use the sequence in the example below to determine the cause of an exception.

Example 3-3: Determining Exception Cause Without Extra Exception Information

```
/* With an internal interrupt controller, check for interrupt
   exceptions. With an external interrupt controller, ipending is
   always 0, and this check can be omitted. */
if (estatus.PIE == 1 and ipending != 0) {
   handle interrupt

/* Decode exception from instruction */
/* Note: Because the exception register is included with the MMU and */
/* MPU, you never need to determine MMU or MPU exceptions by decoding */
} else {
   decode instruction at $ea-4
   if (instruction is trap)
      handle trap exception
   else if (instruction is load or store)
      handle misaligned data address exception
   else if (instruction is branch, bret, callr, eret, jmp, or ret)
      handle misaligned destination address exception
   else if (instruction is unimplemented)
      handle unimplemented instruction exception
   else if (instruction is illegal)
      handle illegal instruction exception
   else if (instruction is divide) {
      if (denominator == 0)
```

```
            handle division error exception
         else if (instruction is signed divide and numerator == 0x80000000
                                                and denominator == 0xffffffff)
            handle division error exception
         }
      }

      /* Not any known exception */
      } else {
         handle unknown exception (If internal interrupt controller
            is implemented, could be spurious interrupt)
      }
   }
```

/f Exception Processing

The CAUSE field of the exception register contains a code for the highest-priority exception occurring at the time. The BADDR field of the badaddr register contains the byte instruction address or data address for certain exceptions.

Refer to the Exceptions table for more information in the Exception Overview section.

Note: External interrupts do not set exception.CAUSE.

To determine the cause of an exception, simply read the cause of the exception from exception.CAUSE and then transfer control to the appropriate exception routine.

/e Exception Processing

Example 3-4: Determining Exception Cause for /e Exception Processing

```
/* With an internal interrupt controller, check for interrupt
   exceptions. With an external interrupt controller, ipending is
   always 0, and this check can be omitted. */
if (estatus.PIE == 1 and ipending != 0) {
   handle interrupt

/* Decode exception from instruction */
/* Note: Because the exception register is included with the MMU and */
/* MPU, you never need to determine MMU or MPU exceptions by decoding */
} else {
   decode instruction at $ea-4
   if (instruction is trap)
      handle trap exception
   else if (instruction is load or store)
      handle misaligned data address exception
   else if (instruction is branch, bret, callr, eret, jmp, or ret)
      handle misaligned destination address exception
   else if (instruction is unimplemented)
      handle unimplemented instruction exception
   else if (instruction is illegal)
      handle illegal instruction exception
   else if (instruction is divide) {
      if (denominator == 0)
         handle division error exception
      else if (instruction is signed divide and numerator == 0x80000000
                                                and denominator == 0xffffffff)
         handle division error exception
      }
   }
```

```
    /* Not any known exception */
    } else {
       handle unknown exception (If internal interrupt controller
          is implemented, could be spurious interrupt)
    }
 }
```

Handling Nested Exceptions

The processor supports several types of nested exceptions, depending on which optional features are implemented. Nested exceptions can occur under the following circumstances:

- An exception handler enables maskable interrupts
- An EIC is present, and an NMI occurs
- An EIC is present, and the processor is configured to keep maskable interrupts enabled when taking an interrupt
- An exception handler triggers an instruction-related exception

  For details about when the processor takes exceptions, refer to "Exception Processing Flow" on page 3–44.

For details about unimplemented instructions, refer to the *Processor Architecture* chapter of the *Processor Reference Handbook*.

For details about MMU and MPU exceptions, refer to the Instruction-Related Exceptions section of this chapter.

A system can be designed to eliminate the possibility of nested exceptions. However, if nested exceptions are possible, the exception handlers must be carefully written to prevent each handler from corrupting the context in which a pre-empted handler runs.

If an exception handler issues a `trap` instruction, an optional instruction, or an instruction which could generate an MMU or MPU exception, it must save and restore the contents of the `estatus` and `ea` registers.

Related Information

- **Instruction-Related Exceptions** on page 3-51
- **Processor Architecture** on page 2-1

Nested Exceptions with the Internal Interrupt Controller

You can enable nested exceptions in each exception handler on a case-by-case basis. If you want to allow a given exception handler to be pre-empted, set `status.PIE` to 1 near the beginning of the handler. Enabling maskable interrupts early in the handler minimizes the worst-case latency of any nested exceptions.

Note: Ensure that all pre-empting handlers preserve the register contents.

Nested Exceptions with an External Interrupt Controller

With an EIC, handling of nested interrupts is more sophisticated than with the internal interrupt controller. Handling of noninterrupt exceptions, however, is the same.

When individual external interrupts have dedicated shadow register sets, the processor supports fast interrupt handling with no overhead for saving register contents. To take full advantage of fast interrupt

handling, system software must set up certain conditions. With the following conditions satisfied, ISRs need not save and restore register contents on entry and exit:

- Automatic nested interrupts are enabled.
- Each interrupt is assigned to a dedicated shadow register set.
- All interrupts with the same RIL are assigned to dedicated shadow register sets.
- Multiple interrupts with different RILs can be assigned to a single shadow register set. However, with multiple register sets, you must not allow the RILs assigned to one shadow register set to overlap the RILs assigned to another register set.

  The following tables demonstrate the validity of register set assignments when preemption within a register set is enabled.

Table 3-49: Example of Illegal RIL Assignment

RIL	Register Set 1	Register Set 2
1	IRQ0	
2	IRQ1	
3		IRQ2
4	IRQ3	
5		IRQ4
6		IRQ5
7		IRQ6

Table 3-50: Example of Legal RIL Assignment

RIL	Register Set 1	Register Set 2
1	IRQ0	
2	IRQ1	
3	IRQ3	
4		IRQ2
5		IRQ4
6		IRQ5
7		IRQ6

Note: Noninterrupt exception handlers must always save and restore the register contents, because they run in the normal register set.

Multiple interrupts can share a register set, with some loss of performance. There are two techniques for sharing register sets:

- Set `status.RSIE` to 0. When an ISR is running in a given register set, the processor does not take any maskable interrupt assigned to the same register set. Such interrupts must wait for the running ISR to complete, regardless of their interrupt level.

Note: This technique can result in a priority inversion.

- Ensure that each ISR saves and restores registers on entry and exit, and set `status.RSIE` to 1 after registers are saved. When an ISR is running in a given register set, the processor takes an interrupt in the same register set if it has a higher interrupt level.

The processor disables interrupts when taking a maskable interrupt (nonmaskable interrupts always disable maskable interrupts). Individual ISRs can re-enable nested interrupts by setting `status.PIE` to 1, as described in the Nested "Exceptions with Internal Interrupt Controller" section of this chapter.

Related Information

Nested Exceptions with the Internal Interrupt Controller on page 3-62

Handling Nonmaskable Interrupts

Writing an NMI handler involves the same basic techniques as writing any other interrupt handler. However, nonmaskable interrupts always preempt maskable interrupts, and cannot be preempted. This knowledge can simplify handler design in some ways, but it means that an NMI handler can have a significant impact on overall interrupt latency. For the best system performance, perform the absolute minimum of processing in your NMI handlers, and defer less-critical processing to maskable interrupt handlers or foreground software.

NMIs leave intact the processor state associated with maskable interrupts and other exceptions, as well as normal, nonexception processing, when each NMI is assigned to a dedicated shadow register set. Therefore, NMIs can be handled transparently.

Note: If not assigned to a dedicated shadow register set, an NMI can overwrite the processor status associated with exception processing, making it impossible to return to the interrupted exception.

Note: Do not set `status.PIE` in a nonmaskable ISR. If `status.PIE` is set, a maskable interrupt can pre-empt an NMI, and the processor exits NMI mode. It cannot be returned to NMI mode until the next nonmaskable interrupt.

Masking and Disabling Exceptions

The processor provides several methods for temporarily turning off some or all exceptions from software. The available methods depend on the hardware configuration. This section discusses all potentially available methods.

Disabling Maskable Interrupts

Software can disable and enable maskable interrupts with the `status.PIE` bit. When `PIE` = 0, maskable interrupts are ignored. When `PIE` = 1, internal and maskable external interrupts can be taken, depending on the status of the interrupt controller.

Masking Interrupts with an External Interrupt Controller

Typical EIC implementations allow system software to mask individual interrupts. The method of masking individual interrupts is implementation-specific.

The `status.IL` field controls what level of external maskable interrupts can be serviced. The processor services a maskable interrupt only if its requested interrupt level is greater than `status.IL`.

An ISR can make run-time adjustments to interrupt nesting by manipulating `status.IL`. For example, if an ISR is running at level 5, to temporarily allow pre-emption by another level 5 interrupt, it can set `status.IL` to 4.

To enable all external interrupts, set `status.IL` to 0. To disable all external interrupts, set `status.IL` to 63.

Masking Interrupts with the Internal Interrupt Controller

The `ienable` register controls the handling of internal hardware interrupts. Each bit of the `ienable` register corresponds to one of the interrupt inputs, `irq0` through `irq31`. A value of one in bit n means that the corresponding `irqn` interrupt is enabled; a bit value of zero means that the corresponding interrupt is disabled.

Refer to the "Exception Processing" section of this chapter for more information.

An ISR can adjust `ienable` so that IRQs of equal or lower priority are disabled. Refer to the "Handling Nested Exceptions" section of this chapter for more information.

- **Exception Processing** on page 3-42

Returning From Interrupt and Instruction-Related Exceptions

The `eret` instruction is used to resume execution at the pre-exception address.

You must ensure that when an exception handler modifies registers, they are restored when it returns. This can be taken care of in either of the following ways:

- In the case of ISRs, if the EIC interface and shadow register sets are implemented, and the ISR has a dedicated register set, no software action is required. The processor returns to the previous register set when it executes `eret`, which restores the register contents.
- For details, refer to the "Nested Exceptions with an External Interrupt Controller" section of this chapter.
- In the case of noninterrupt exceptions, for ISRs in a system with the internal interrupt controller, and for ISRs without a dedicated shadow register set, the exception handler must save registers on entry and restore them on exit. Saving the register contents on the stack is a typical, re-entrant implementation.

Note: It is not necessary to save and restore the exception temporary (`et` or `r24`) register.

When executing the `eret` instruction, the processor performs the following tasks:

1. Restores the previous contents of `status` as follows:
   - If `status.CRS` is 0, copies `estatus` to `status`
   - If `status.CRS` is nonzero, copies `sstatus` to `status`
2. Transfers program execution to the address in the `ea` register (`r29`) in the register set specified by the original value of `status.CRS`.

Note: The `eret` instruction can cause the processor to exit NMI mode. However, it cannot make the processor enter NMI mode. In other words, if `status.NMI` is 0 and `estatus.NMI` (or `sstatus.NMI`) is 1, after an `eret`, `status.NMI` is still 0. This restriction prevents the processor from accidentally entering NMI mode.

Note: When the EIC interface and shadow register sets are implemented on the Nios II core, you must ensure that your software, including ISRs, is built with the version of the GCC compiler included in Nios II EDS version 9.0 or later. Earlier versions have an implementation of the `eret` instruction that is incompatible with shadow register sets.

Related Information

Nested Exceptions with the Internal Interrupt Controller on page 3-62

Return Address Considerations

The return address requires some consideration when returning from exception processing routines. After an exception occurs, ea contains the address of the instruction following the point where the exception occurred.

When returning from instruction-related exceptions, execution must resume from the instruction following the instruction where the exception occurred. Therefore, ea contains the correct return address.

On the other hand, hardware interrupt exceptions must resume execution from the interrupted instruction itself. In this case, the exception handler must subtract 4 from ea to point to the interrupted instruction.

Memory and Peripheral Access

Nios II addresses are 32 bits, allowing access up to a 4-gigabyte address space. Nios II core implementations without MMUs restrict addresses to 31 bits or fewer. The MMU supports the full 32-bit physical address.

Nios II addresses are 32 bits, allowing access up to a 4-gigabyte address space. The MMU supports the full 32-bit physical address. Bit 31 bypass is optional, you can access full 32-bit addressing without the MMU.

For details, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Peripherals, data memory, and program memory are mapped into the same address space. The locations of memory and peripherals within the address space are determined at system generation time. Reading or writing to an address that does not map to a memory or peripheral produces an undefined result.

The processor's data bus is 32 bits wide. Instructions are available to read and write byte, half-word (16-bit), or word (32-bit) data.

The Nios II architecture uses little-endian byte ordering. For data wider than 8 bits stored in memory, the more-significant bits are located in higher addresses.

The Nios II architecture supports register and immediate addressing.

Related Information

Core Implementation Details on page 5-1

Cache Memory

The Nios II architecture and instruction set accommodate the presence of data cache and instruction cache memories. Cache management is implemented in software by using cache management instructions. Instructions are provided to initialize the cache, flush the caches whenever necessary, and to bypass the data cache to properly access memory-mapped peripherals.

The Nios II architecture provides the following mechanisms to bypass the cache:

- When no MMU is present, bit 31 of the address is reserved for bit-31 cache bypass. With bit-31 cache bypass, the address space of processor cores is 2 GB, and the high bit of the address controls the caching of data memory accesses.
- When the MMU is present, cacheability is controlled by the MMU, and bit 31 functions as a normal address bit. For details, refer to the Address Space and Memory Partitions section , and the TLB Organization section of this chapter.
- Cache bypass instructions, such as `ldwio` and `stwio`.

- When no MMU is present, bit 31 of the address is reserved for the optimal bit-31 cache bypass. With bit-31 cache bypass, the address space of processor cores is 2 GB, and the high bit of the address controls the caching of data memory accesses.
- When the MMU is present, cacheability is controlled by the MMU, and bit 31 functions as a normal address bit. For details, refer to the Address Space and Memory Partitions section , and the TLB Organization section of this chapter.
- Cache bypass instructions, such as `ldwio` and `stwio`.

Refer to the *Nios II Core Implementation Details* chapter of the *Processor Reference Handbook* for details of which processor cores implement bit-31 cache bypass.

Refer to *Instruction Set Reference* chapter of the *Nios II Processor Reference Handbook* for details of the cache bypass instructions.

Code written for a processor core with cache memory behaves correctly on a processor core without cache memory. The reverse is not true. If it is necessary for a program to work properly on multiple processor core implementations, the program must behave as if the instruction and data caches exist. In systems without cache memory, the cache management instructions perform no operation, and their effects are benign.

For a complete discussion of cache management, refer to the*Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Some consideration is necessary to ensure cache coherency after processor reset. Refer to "Reset Exceptions" section of this chapter for more information.

For information about the cache architecture and the memory hierarchy refer to the *Processor Architecture* chapter of the *Processor Reference Handbook*.

Virtual Address Aliasing

A virtual address alias occurs when two virtual addresses map to the same physical address. When an MMU and caches are present and the caches are larger than a page (4 KB), the operating system must prevent illegal virtual address aliases. Because the caches are virtually-indexed and physically-tagged, a portion of the virtual address is used to select the cache line. If the cache is 4 KB or less in size, the portion of the virtual address used to select the cache line fits with bits 11:0 of the virtual address which have the same value as bits 11:0 of the physical address (they are untranslated bits of the page offset). However, if the cache is larger than 4 KB, bits beyond the page offset (bits 12 and up) are used to select the cache line and these bits are allowed to be different than the corresponding physical address.

For example, in a 64-KB direct-mapped cache with a 16-byte line, bits 15:4 are used to select the line. Assume that virtual address `0x1000` is mapped to physical address `0xF000` and virtual address `0x2000` is also mapped to physical address `0xF000`. This is an illegal virtual address alias because accesses to virtual address `0x1000` use line 0x1 and accesses to virtual address `0x2000` use line 0x2 even though they map to the same physical address. This results in two copies of the same physical address in the cache. With an n-byte direct-mapped cache, there could be n/4096 copies of the same physical address in the cache if illegal

virtual address aliases are not prevented. The bits of the virtual address that are used to select the line and are translated bits (bits 12 and up) are known as the color of the address. An operating system avoids illegal virtual address aliases by ensuring that if multiple virtual addresses map the same physical address, the virtual addresses have the same color. Note though, the color of the virtual addresses does not need to be the same as the color as the physical address because the cache tag contains all the bits of the PFN.

Instruction Set Categories

This section introduces the Nios II instructions categorized by type of operation performed.

Data Transfer Instructions

The architecture is a load-store architecture. Load and store instructions handle all data movement between registers, memory, and peripherals. Memories and peripherals share a common address space. Some processor cores use memory caching as well as write buffering to improve memory bandwidth. The architecture provides instructions for both cached and uncached accesses.

Table 3-51: Wide Data Transfer Instructions

Instruction	Description
`ldw` `stw`	The `ldw` and `stw` instructions load and store 32-bit data words from/to memory. The effective address is the sum of a register's contents and a signed immediate value contained in the instruction. Memory transfers can be cached or buffered to improve program performance. This caching and buffering might cause memory cycles to occur out of order, and caching might suppress some cycles entirely. Data transfers for I/O peripherals should use `ldwio` and `stwio`.

`ldw`
`io`
`stw`
`io`
	`ldwio` and `stwio` instructions load and store 32-bit data words from/to peripherals without caching and buffering. Access cycles for `ldwio` and `stwio` instructions are guaranteed to occur in instruction order and are never suppressed.

Table 3-52: Narrow Data Transfer Instructions

Instruction	Description

`ldb`
`ldbu`
`stb`
`ldh`
`ldhu`
`sth`
	`ldb`, `ldbu`, `ldh` and `ldhu` load a byte or half-word from memory to a register. `ldb` and `ldh` sign-extend the value to 32 bits, and `ldbu` and `ldhu` zero-extend the value to 32 bits.
	`stb` and `sth` store byte and half-word values, respectively.
	Memory accesses can be cached or buffered to improve performance. To transfer data to I/O peripherals, use the io versions of the instructions, described in the following table cell.

Instruction	Description
ldbio ldbuio stbio ldhio ldhuio sthio	These operations load/store byte and half-word data from/to peripherals without caching or buffering.

Arithmetic and Logical Instructions

Logical instructions support and, or, xor, and nor operations. Arithmetic instructions support addition, subtraction, multiplication, and division operations.

Table 3-53: Arithmetic and Logical Instructions

Instruction	Description
and or xor nor	These are the standard 32-bit logical operations. These operations take two register values and combine them bit-wise to form a result for a third register.
andi ori xori	These operations are immediate versions of the and, or, and xor instructions. The 16-bit immediate value is zero-extended to 32 bits, and then combined with a register value to form the result.
andhi orhi xorhi	In these versions of and, or, and xor, the 16-bit immediate value is shifted logically left by 16 bits to form a 32-bit operand. Zeroes are shifted in from the right.
add sub mul div divu	These are the standard 32-bit arithmetic operations. These operations take two registers as input and store the result in a third register.
addi subi muli	These instructions are immediate versions of the add, sub, and mul instructions. The instruction word includes a 16-bit signed value.
mulxss mulxuu	These instructions provide access to the upper 32 bits of a 32x32 multiplication operation. Choose the appropriate instruction depending on whether the operands should be treated as signed or unsigned values. It is not necessary to precede these instructions with a mul.

Instruction	Description
mulxsu	This instruction is used in computing a 128-bit result of a 64x64 signed multiplication.

Move Instructions

These instructions provide move operations to copy the value of a register or an immediate value to another register.

Table 3-54: Move Instructions

Instruction	Description
mov movhi movi movui movia	mov copies the value of one register to another register. movi moves a 16-bit signed immediate value to a register, and sign-extends the value to 32 bits. movui and movhi move a 16-bit immediate value into the lower or upper 16-bits of a register, inserting zeros in the remaining bit positions. Use movia to load a register with an address.

Comparison Instructions

The Nios II architecture supports a number of comparison instructions. All of these compare two registers or a register and an immediate value, and write either one (if true) or zero to the result register. These instructions perform all the equality and relational operators of the C programming language.

Table 3-55: Comparison Instructions

Instruction	Description
cmpeq	==
cmpne	!=
cmpge	signed >=
cmpgeu	unsigned >=
cmpgt	signed >
cmpgtu	unsigned >
cmple	unsigned <=

Instruction	Description
cmpleu	unsigned <=
cmplt	signed <
cmpltu	unsigned <
cmpeqi cmpnei cmpgei cmpgeui cmpgti cmpgtui cmplei cmpleui cmplti cmpltui	These instructions are immediate versions of the comparison operations. They compare the value of a register and a 16-bit immediate value. Signed operations sign-extend the immediate value to 32-bits. Unsigned operations fill the upper bits with zero.

Shift and Rotate Instructions

The following instructions provide shift and rotate operations. The number of bits to rotate or shift can be specified in a register or an immediate value.

Table 3-56: Shift and Rotate Instructions

Instruction	Description
rol ror roli	The rol and roli instructions provide left bit-rotation. roli uses an immediate value to specify the number of bits to rotate. The ror instructions provides right bit-rotation. There is no immediate version of ror, because roli can be used to implement the equivalent operation.
sll slli sra srl srai srli	These shift instructions implement the << and >> operators of the C programming language. The sll, slli, srl, srli instructions provide left and right logical bit-shifting operations, inserting zeros. The sra and srai instructions provide arithmetic right bit-shifting, duplicating the sign bit in the most significant bit. slli, srli and srai use an immediate value to specify the number of bits to shift.

Program Control Instructions

The Nios II architecture supports the unconditional jump, branch, and call instructions. These instructions do not have delay slots.

Table 3-57: Unconditional Jump and Call Instructions

Instruction	Description
call	This instruction calls a subroutine using an immediate value as the subroutine's absolute address, and stores the return address in register ra.

Instruction	Description
`callr`	This instruction calls a subroutine at the absolute address contained in a register, and stores the return address in register `ra`. This instruction serves the roll of dereferencing a C function pointer.
`ret`	The `ret` instruction is used to return from subroutines called by `call` or `callr`. `ret` loads and executes the instruction specified by the address in register `ra`.
`jmp`	The `jmp` instruction jumps to an absolute address contained in a register. `jmp` is used to implement switch statements of the C programming language.
`jmpi`	The `jmpi` instruction jumps to an absolute address using an immediate value to determine the absolute address.
`br`	This instruction branches relative to the current instruction. A signed immediate value gives the offset of the next instruction to execute.

The conditional branch instructions compare register values directly, and branch if the expression is true. The conditional branches support the following equality and relational comparisons of the C programming language:

- == and !=
- < and <= (signed and unsigned)
- > and >= (signed and unsigned)

The conditional branch instructions do not have delay slots.

Table 3-58: Conditional Branch Instructions

Instruction	Description

`bge`
`bgeu`
`bgt`
`bgtu`
`ble`
`bleu`
`blt`
`bltu`
`beq`
`bne`
	These instructions provide relative branches that compare two register values and branch if the expression is true. Refer to the "Comparison Instructions" section of this chapter for a description of the relational operations implemented.

Related Information

Comparison Instructions on page 3-70

Other Control Instructions

Table 3-59: Other Control Instructions

Instruction	Description
`trap` `eret`	The `trap` and `eret` instructions generate and return from exceptions. These instructions are similar to the `call`/`ret` pair, but are used for exceptions. `trap` saves the `status` register in the `estatus` register, saves the return address in the `ea` register, and then transfers execution to the general exception handler. `eret` returns from exception processing by restoring `status` from `estatus`, and executing the instruction specified by the address in `ea`.
`break` `bret`	The `break` and `bret` instructions generate and return from breaks. `break` and `bret` are used exclusively by software debugging tools. Programmers never use these instructions in application code.
`rdctl` `wrctl`	These instructions read and write control registers, such as the `status` register. The value is read from or stored to a general-purpose register.

`flushd`
`flushda`
`flushi`
`initd`
`initda`
`initi`
	These instructions are used to manage the data and instruction cache memories.

`flushp`	This instruction flushes all prefetched instructions from the pipeline. This is necessary before jumping to recently-modified instruction memory.
`sync`	This instruction ensures that all previously-issued operations have completed before allowing execution of subsequent load and store operations.
`rdprs` `wrprs`	These instructions read and write a general-purpose registers between the current register set and another register set. `wrprs` can set `r0` to 0 in a shadow register set. System software must use `wrprs` to initialize `r0` to 0 in each shadow register set before using that register set.

Custom Instructions

The `custom` instruction provides low-level access to custom instruction logic. The inclusion of custom instructions is specified with the Processor parameter editor in , and the function implemented by custom instruction logic is design dependent.

For more information, refer to the "Custom Instructions" section of the *Processor Architecture* chapter of the *Processor Reference Handbook*

For continued more information refer to the *Nios II Custom Instruction User Guide.*

Machine-generated C functions and assembly language macros provide access to custom instructions, and hide implementation details from the user. Therefore, most software developers never use the `custom` assembly language instruction directly.

Related Information

- **Nios II Custom Instruction User Guide**
- **Processor Architecture** on page 2-1

No-Operation Instruction

The Nios II assembler provides a no-operation instruction, `nop`.

Potential Unimplemented Instructions

Some processor cores do not support all instructions in hardware. In this case, the processor generates an exception after issuing an unimplemented instruction. Only the following instructions can generate an unimplemented instruction exception:

- `mul`
- `muli`
- `mulxss`
- `mulxsu`
- `mulxuu`
- `div`
- `divu`
- `initda`

All other instructions are guaranteed not to generate an unimplemented instruction exception.

An exception routine must exercise caution if it uses these instructions, because they could generate another exception before the previous exception is properly handled.

Refer to the "Unimplemented Instruction" section of this chapter for more information regarding unimplemented instruction processing.

Programming Model Revision History

Table 3-60: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Removed extra exception information option from chapter.
April 2015	2015.04.02	• Removed obsolete devices: Cyclone II and Stratix II • Removed config.ANI flag from chapter

Date	Version	Changes
February 2014	13.1.0	• Added information on ECC support. • Removed HardCopy information. • Removed references to SOPC Builder.
May 2011	11.0.0	Added references to new system integration tool.
December 2010	10.1.0	Maintenance release.
July 2010	10.0.0	Maintenance release.
November 2009	9.1.0	• Added external interrupt controller interface information. • Added shadow register set information.
March 2009	9.0.0	Maintenance release.
November 2008	8.1.0	Maintenance release.
May 2008	8.0.0	Added text to describe the MMU, MPU, and advanced exceptions.
October 2007	7.2.0	• Reworked text to refer to break and reset as exceptions. • Grouped exceptions, break, reset, and interrupts all under Exception Processing. • Added table showing all Nios II exceptions (by priority). • Removed "ctl" references to control registers. • Added `jmpi` instruction to tables.
May 2007	7.1.0	• Added table of contents to Introduction section. • Added Referenced Documents section.
March 2007	7.0.0	Maintenance release.
November 2006	6.1.0	Maintenance release.
May 2006	6.0.0	Maintenance release.
October 2005	5.1.0	Maintenance release.
May 2005	5.0.0	Maintenance release.
September 2004	1.1	• Added details for new control register `ctl5`. • Updated details of debug and break processing to reflect new behavior of the `break` instruction.
May 2004	1.0	Initial release.

Document Version	Changes
2019.12.20	• Corrections to BASE field description in *The mpubase Register* • Correction to *The LIMIT Field*
2019.04.30	Maintenance release

Document Version	Changes
2018.04.18	• Implemented editorial enhancements. • Corrected information about `mpubase`, and `mpuacc` register. • Corrected the Table: *MASK Region Size Encodings*.
2016.10.28	Removed extra exception information option.
2015.04.02	Initial release

Instantiating the Nios II Processor 4

2016.10.28

NII51004

This chapter describes the Nios® II Processor parameter editor in Qsys. The Nios II Processor parameter editor allows you to specify the processor features for a particular Nios II hardware system. This chapter covers the features of the Nios II processor that you can configure with the Nios II Processor parameter editor; it is not a user guide for creating complete Nios II processor systems.

To get started designing custom Nios II systems, refer to the Nios II Hardware Development Tutorial.

Development kits for Altera devices, available on the All Development Kits page of the Altera website, also provide ready-made hardware design examples that demonstrate different configurations of the Nios II processor.

Related Information

- **Memory Protection Unit Settings** on page 4-5

Core Selection

The main purpose of the **Core Nios II** tab is to select the processor core. The core you select on this tab affects other options available on this and other tabs.

Altera offers the following Nios II cores:

- **Nios II/f**—The Nios II/f fast core is designed for fast performance. As a result, this core presents the most configuration options allowing you to fine tune the processor for performance.
- **Nios II/s**—The Nios II/s standard core is designed for small size while maintaining performance.
- **Nios II/e**—The Nios II/e economy core is designed to achieve the smallest possible core size. As a result, this core has a limited feature set, and many settings are not available when the Nios II/e core is selected.

The **Core Nios II** tab displays a selector guide table that lists the basic properties of each core.

For implementation information about each core, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Core Implementation Details on page 5-1

Multiply and Divide Settings

The Nios II/s and Nios II/f cores offer hardware multiply and divide options. You can choose the best option to balance embedded multiplier usage, logic element (LE) usage, and performance.

The **Hardware multiplication type** parameter for each core provides the following list:

- **DSP Block**—Include DSP block multipliers in the arithmetic logic unit (ALU). This option is only selectable when targeting devices that have DSP block multipliers.
- **Embedded Multipliers—**Include embedded multipliers in the ALU. This option is only present when targeting FPGA devices that have embedded multipliers.
- **Logic Elements**—Include LE-based multipliers in the ALU. This option achieves high multiply performance without consuming embedded multiplier resources, but with reduced f_{MAX}.
- **None**—This option conserves logic resources by eliminating multiply hardware. Multiply operations are implemented in software.

Note: Shift operations use the multiplier. So, **Hardware multiplication type** affects shift instruction speed.

Turning on **Hardware divide** includes LE-based divide hardware in the ALU. The **Hardware divide** option achieves much greater performance than software emulation of divide operations.

For information about the performance effects of the hardware multiply and divide options, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Core Implementation Details on page 5-1

Reset Vector

Parameters in this section select the memory module where the reset code (boot loader) resides, and the location of the reset vector (reset address). The reset vector cannot be configured until your system memory components are in place.

The **Reset vector memory** list, which includes all memory modules mastered by the Nios II processor, selects the reset vector memory module. In a typical system, select a nonvolatile memory module for the reset code.

Note: Qsys provides an **Absolute** option, which allows you to specify an absolute address in **Reset vector offset**. Use an absolute address when the memory storing the reset handler is located outside of the processor system and subsystems of the processor system.

Reset vector offset specifies the location of the reset vector relative to the memory module's base address. Qsys calculates the physical address of the reset vector when you modify the memory module, the offset, or the memory module's base address. In Qsys, **Reset vector** displays the read-only, calculated address. The address is always a physical address, even when an MMU is present.

For information about reset exceptions, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Programming Model on page 3-1

General Exception Vector

Parameters in this section select the memory module where the general exception vector (exception address) resides, and the location of the general exception vector. The general exception vector cannot be configured until your system memory components are in place.

The **Exception vector memory** list, which includes all memory modules mastered by the Nios II processor, selects the exception vector memory module. In a typical system, select a low-latency memory module for the exception code.

Note: Qsys provides an **Absolute** option, which allows you to specify an absolute address in **Exception vector offset**. Use an absolute address when the memory storing the exception handler is located outside of the processor system and subsystems of the processor system.

Exception vector offset specifies the location of the exception vector relative to the memory module's base address. Qsys calculates the physical address of the exception vector when you modify the memory module, the offset, or the memory module's base address. In Qsys, **Exception vector** displays the read-only, calculated address.. The address is always a physical address, even when an MMU is present.

For information about exceptions, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Programming Model on page 3-1

Memory Management Unit Settings

The Nios II/f core offers a memory management unit (MMU) to support full-featured operating systems. Turning on **Include MMU** includes the Nios II MMU in your Nios II hardware system.

Note: Do not include an MMU in your Nios II system unless your operating system requires it. The MMU is only useful with software that takes advantage of it. Many Nios II systems involve simpler system software, such as Altera HAL or MicroC/OS-II. Such software is unlikely to function correctly with an MMU-based Nios II processor.

Fast TLB Miss Exception Vector

The fast TLB miss exception vector is a special exception vector used exclusively by the MMU to handle TLB miss exceptions. Parameters in this section select the memory module where the fast TLB miss exception vector (exception address) resides, and the location of the fast TLB miss exception vector. The fast TLB miss exception vector cannot be configured until your system memory components are in place.

The Fast TLB Miss Exception vector memory list, which includes all memory modules mastered by the Nios II processor, selects the exception vector memory module. In a typical system, select a low-latency memory module for the exception code.

Note: Qsys provides an Absolute option, which allows you to specify an absolute address in Fast TLB Miss Exception vector offset. Use an absolute address when the memory storing the exception handler is located outside of the processor system and subsystems of the processor system.

Fast TLB Miss Exception vector offset specifies the location of the exception vector relative to the memory module's base address. Qsys calculates the physical address of the exception vector when you modify the memory module, the offset, or the memory module's base address. In Qsys, Fast TLB Miss Exception vector displays the readonly, calculated address. The address is always a physical address, even when an MMU is present.

Note: The Nios II MMU is optional and mutually exclusive from the Nios II MPU. Nios II systems can include either an MMU or MPU, but cannot include both an MMU and MPU in the same design.

For information about the Nios II MMU, refer to the *Programming Model* chapter of the Nios II Processor Reference Handbook.

To function correctly with the MMU, the base physical address of all exception vectors (reset, general exception, break, and fast TLB miss) must point to low physical memory so that hardware can correctly map their virtual addresses into the kernel partition. This restriction is enforced by the Nios II Processor parameter editor.

Related Information

Programming Model on page 3-1

Memory Protection Unit Settings

The Nios II/f core offers a memory protection unit (MPU) to support operating systems and runtime environments that desire memory protection without the overhead of virtual memory management. Turning on **Include MPU** includes the Nios II MPU in your Nios II hardware system.

Note: The Nios II MPU is optional and mutually exclusive from the Nios II MMU. Nios II systems can include either an MPU or MMU, but cannot include both an MPU and MMU in the same design.

For information about the Nios II MPU, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Programming Model on page 3-1

Caches and Memory Interfaces Tab

The **Caches and Memory Interfaces** tab allows you to configure the cache and tightly-coupled memory usage for the instruction and data master ports.

Table 4-2: Caches and Memory Interfaces Tab Parameters

Name	Description
Instruction Master	
Instruction cache	Refer to the "Instruction Master Settings" Section.
Burst transfers	
Number of tightly coupled instruction master port(s)	
Data Master	

Name	Description
Omit data master port	Refer to the "Data Master" Settings.
Data cache	
Data cache line size	
Burst transfers	
Data cache victim buffer implementation	
Number of tightly coupled instruction master port(s)	

The following sections describe the configuration settings available.

Related Information

- **Data Master Settings** on page 4-7
- **Instruction Master Settings** on page 4-6

Instruction Master Settings

The **Instruction Master** parameters provide the following options for the Nios II/f and Nios II/s cores:

- **Instruction cache**—Specifies the size of the instruction cache. Valid sizes are from **512 bytes** to **64 KBytes**, or **None**.

  Choosing **None** disables the instruction cache, which also removes the Avalon-MM instruction master port from the Nios II processor. In this case, you must include a tightly-coupled instruction memory.
- **Burst transfers** —The Nios II processor can fill its instruction cache lines using burst transfers. Usually you enable bursts on the processor's instruction master when instructions are stored in DRAM, and disable bursts when instructions are stored in SRAM.

  Bursting to DRAM typically improves memory bandwidth, but might consume additional FPGA resources. Be aware that when bursts are enabled, accesses to slaves might go through additional hardware (called burst adapters) which might decrease your f_{MAX}.

  When the Nios II processor transfers execution to the first word of a cache line, the processor fills the line by executing a sequence of word transfers that have ascending addresses, such as 0, 4, 8, 12, 16, 20, 24, 28.

  However, when the Nios II processor transfers execution to an instruction that is not the first word of a cache line, the processor fetches the required (or "critical") instruction first, and then fills the rest of the cache line. The addresses of a burst increase until the last word of the cache line is filled, and then continue with the first word of the cache line. For example, with a 32-byte cache line, transferring control to address 8 results in a burst with the following address sequence: 8, 12, 16, 20, 24, 28, 0, 4.
- **Data cache victim buffer implementation**—Specifies whether to use RAM or registers. The data cache victim buffer temporarily holds a dirty cache line while the data is written back to external memory.
- **Number of tightly coupled instruction master port(s)** (**Include tightly coupled instruction master port(s)**)—Specifies one to four tightly-coupled instruction master ports for the Nios II processor. In Qsys, select the number from the **Number of tightly coupled instruction master port(s)** list. Tightly-coupled memory ports appear on the connection panel of the Nios II processor on the Qsys **System Contents** tab. You must connect each port to exactly one memory component in the system.

Data Master Settings

The **Data Master** parameters provide the following options for the Nios II/f core:

- **Omit data master port**—Removes the Avalon-MM data master port from the Nios II processor. The port is only successfully removed when **Data cache** is set to **None** and **Number of tightly coupled data master port(s)** is greater than zero.

Note: Although the Nios II processor can operate entirely out of tightly-coupled memory without the need for Avalon-MM instruction or data masters, software debug is not possible when either the Avalon-MM instruction or data master is omitted.

- **Data cache**—Specifies the size of the data cache. Valid sizes are from **512 bytes** to **64 KBytes**, or **None**. Depending on the value specified for **Data cache**, the following options are available:
  - **Data cache line size**—Valid sizes are **4 bytes**, **16 bytes**, or **32 bytes**.
  - **Burst transfers** —The Nios II processor can fill its data cache lines using burst transfers. Usually you enable bursts on the processor's data bus when processor data is stored in DRAM, and disable bursts when processor data is stored in SRAM.

    Bursting to DRAM typically improves memory bandwidth but might consume additional FPGA resources. Be aware that when bursts are enabled, accesses to slaves might go through additional hardware (called burst adapters) which might decrease your f_{MAX}.

    Bursting is only enabled for data cache line sizes greater than 4 bytes. The burst length is 4 for a 16 byte line size and 8 for a 32 byte line size. Data cache bursts are always aligned on the cache line boundary. For example, with a 32-byte Nios II data cache line, a cache miss to the address 8 results in a burst with the following address sequence: 0, 4, 8, 12, 16, 20, 24 and 28.
- **Number of tightly coupled data master port(s)** (**Include tightly coupled data master port(s)**)—Specifies one to four tightly-coupled data master ports for the Nios II processor. In Qsys, select the number from the **Number of tightly coupled data master port(s)** list. Tightly-coupled memory ports appear on the connection panel of the Nios II processor on the Qsys **System Contents** tab. You must connect each port to exactly one memory component in the system.

Advanced Features Tab

The **Advanced Features** tab allows you to enable specialized features of the Nios II processor.

Table 4-3: Advanced Features Tab Parameters

Name	Description
General	
Interrupt controller	Refer to the "Interrupt Controller" Interfaces section.
Number of shadow register sets	Refer to the "Shadow Register Sets" section.
Include cpu_resetrequest and cpu_resettaken signals	Refer to the "Reset Signal"s section.
Assign cpuid control register value manually	Refer to the "Control Registers" section.
cpuid control register value	
Exception Checking	

Name	Description
Illegal instruction	Refer to the "Exception Checking" section.
Division error	
Misaligned memory access	
Extra exception information	
HardCopy Compatibility	
HardCopy compatible	Refer to the "Hardcopy Compatible" section.
ECC	
ECC present	Refer to the "ECC" section.

Related Information

- **ECC** on page 4-10
- **HardCopy Compatible** on page 4-10
- **Exception Checking** on page 4-9
- **Control Registers** on page 4-8
- **Reset Signals** on page 4-8
- **Shadow Register Sets** on page 4-10
- **Interrupt Controller Interfaces** on page 4-9

Reset Signals

The **Include cpu_resetrequest and cpu_resettaken signals** reset signals setting provides the following functionality. When on, the Nios II processor includes processor-only reset request signals. These signals let another device individually reset the Nios II processor without resetting the entire system. The signals are exported to the top level of your system.

Note: You must manually connect these signals to logic external to your Qsys system.

For more information on the reset signals, refer to the *Processor Architecture* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Processor Architecture on page 2-1

Control Registers

The **Assign cpuid control register value manually** control register setting allows you to assign the `cpuid` control register value yourself. In Qsys, the automatically-assigned value is always 0x00000000, so Altera recommends always assigning the value manually.

To assign the value yourself, turn on **Assign cpuid control register value manually** and type a 32-bit value (in hexadecimal or decimal format) in the **cpuid control register value box**.

Related Information

SOPC Builder to Qsys Migration Guidelines

For information about upgrading IDs that were manually-assigned values in Qsys, refer to the SOPC Builder to Qsys Migration Guideline.

Exception Checking

The **Exception Checking** settings provide the following options:

- **Illegal instruction**—When **Illegal instruction** is on, the processor generates an illegal instruction exception when an instruction with an undefined opcode or opcode-extension field is executed.

Note: When your system contains an MMU or MPU, the processor automatically generates illegal instruction exceptions. Therefore, the **Illegal instruction** setting is always disabled when the **Core Nios II** tab **Include MMU** or **Include MPU** are on.

- **Division error**—Division error detection is only available for the Nios II/f core, and only then when **Hardware divide** on the **Core Nios II** tab is on. When divide instructions are not supported by hardware, the **Division error** setting is disabled.

  When **Division error** is on, the processor generates a division error exception when it detects divide instructions that produce a result that cannot be represented in the destination register. This only happens in the following two cases:

  - Divide by zero
  - Divide overflow—A signed division that divides the largest negative number -2147483648 (0x80000000) by -1 (0xffffffff).
- **Misaligned memory access**—Misaligned memory access detection is only available for the Nios II/f core. When **Misaligned memory access** is on, the processor checks for misaligned memory accesses.

Note: When your system contains an MMU or MPU, the processor automatically generates misaligned memory access exceptions. Therefore, the **Misaligned memory access** check box is always disabled when **Include MMU** or **Include MPU** on the **Core Nios II** tab are on.

There are two misaligned memory address exceptions:

- Misaligned data address—Data addresses of load and store instructions are checked for misalignment. A data address is considered misaligned if the byte address is not a multiple of the data width of the load or store instruction (4 bytes for word, 2 bytes for half-word). Byte load and store instructions are always aligned so never generate a misaligned data address exception.
- Misaligned destination address—Destination instruction addresses of `br`, `callr`, `jmp`, `ret`, `eret`, and `bret` instructions are checked for misalignment. A destination instruction address is considered misaligned if the target byte address of the instruction is not a multiple of four.
- **Extra exception information**—When **Extra exception information** is on, nonbreak exceptions store a code in the `CAUSE` field of the `exception` control register to indicate the cause of the exception.

Note: When your system contains an MMU or MPU, the processor automatically generates extra exception information. Therefore, the **Extra exception information** setting is always disabled when the **Core Nios II** tab **Include MMU** or **Include MPU** are on.

Your exception handler can use this code to quickly determine the proper action to take, rather than have to determine the cause of an exception through instruction decoding. Additionally, some exceptions also store the instruction or data address associated with the exception in the `badaddr` register.

For further descriptions of exceptions, exception handling, and control registers, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Programming Model on page 3-1

Interrupt Controller Interfaces

The **Interrupt controller** setting determines which of the following configurations is implemented:

- Internal interrupt controller
- External interrupt controller (EIC) interface

The EIC interface is available only on the Nios II/f core.

Note: When the EIC interface and shadow register sets are implemented on the Nios II core, you must ensure that your software is built with the Nios II Embedded Design Suite (EDS) version 9.0 or higher. Earlier versions have an implementation of the `eret` instruction that is incompatible with shadow register sets.

For details about the EIC interface, refer to "Exception Processing" in the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Programming Model on page 3-1

Shadow Register Sets

The Number of shadow register sets setting determines whether the Nios II core implements shadow register sets. The Nios II core can be configured with up to 63 shadow register sets.

Shadow register sets are available only on the Nios II/f core.

Note: When the EIC interface and shadow register sets are implemented on the Nios II core, you must ensure that your software is built with the Nios II EDS version 9.0 or higher.

For details about shadow register sets, refer to "Registers" in the *Programming Model* chapter of the Nios II Processor Reference Handbook.

Related Information

Programming Model on page 3-1

HardCopy Compatible

The HardCopy Compatible parameter determines whether the instantiated Nios II core is compatible with HardCopy® devices without recompilation. This feature allows you to migrate from an FPGA device to HardCopy device without any RTL changes to the Nios II core. When **HardCopy Compatible** is on, any generated Nios II core and JTAG debug module RAM blocks are not pre-initialized.

Note: When **Device family** on the Qsys **Project Settings** tab is a HardCopy device, **HardCopy Compatible** is automatically turned on and uneditable.

Altera no longer offers HardCopy structured ASIC products for new design starts. Altera continues to support HardCopy for existing designs. Customers can find product documentation for the HardCopy structured ASIC series in the Altera mature devices product listing.

Related Information

Altera ASICs

ECC

ECC is only available for the Nios II/f core and provides ECC support for Nios II internal RAM blocks, such as instruction cache, MMU TLB, and register file. The SECDED ECC algorithm is based on Hamming codes, which detect 1 or 2 bit errors and corrects 1 bit errors. If the Nios II processor does not attempt to correct any errors and only detects them, the ECC algorithm can detect 3 bit errors.

Refer to "ECC" section in the *Nios II Core Implementation Details* chapter for more information about ECC support in the Nios II/f core.

Related Information

Core Implementation Details on page 5-1

MMU and MPU Settings Tab

The **MMU and MPU Settings** tab presents settings for configuring the MMU and MPU on the Nios II processor. You can select the features appropriate for your target application.

Table 4-4: MMU and MPU Settings Tab Parameters

Name	Description
MMU	
Process ID (PID) bits	Refer to the "MMU" section.
Optimize number of TLB entries based on device family	
TLB entries	
TLB Set-Associativity	
Micro DTLB entries	
Micro ITLB entries	
MPU	
Use Limit for region range	Refer to the "MPU" section.
Number of data regions	
Minimum data region size	
Number of instruction regions	
Minimum instruction region size	

Related Information

- **MPU** on page 4-12
- **MMU** on page 4-11

MMU

When **Include MMU** on the **Core Nios II** tab is on, the MMU settings on the **MMU and MPU Settings** tab provide the following options for the MMU in the Nios II/f core. Typically, you should not need to change any of these settings from their default values.

- **Process ID (PID) bits**—Specifies the number of bits to use to represent the process identifier.
- **Optimize number of TLB entries based on device family**—When on, specifies the optimal number of TLB entries to allocate based on the device family of the target hardware and disables **TLB entries**.
- **TLB entries**—Specifies the number of entries in the translation lookaside buffer (TLB).
- **TLB Set-Associativity**—Specifies the number of set-associativity ways in the TLB.
- **Micro DTLB entries**—Specifies the number of entries in the micro data TLB.
- **Micro ITLB entries**—Specifies the number of entries in the micro instruction TLB.

For information about the MMU, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

For specifics on the Nios II/f core, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Related Information

- **Programming Model** on page 3-1
- **Core Implementation Details** on page 5-1

MPU

When **Include MPU** on the **Core Nios II** tab is on, the MPU settings on the **MMU and MPU Settings** tab provide the following options for the MPU in the Nios II/f core.

- **Use Limit for region range—**Controls whether the amount of memory in the region is defined by size or by upper address limit. When on, the amount of memory is based on the given upper address limit. When off, the amount of memory is based on the given size.
- **Number of data regions**—Specifies the number of data regions to allocate. Allowed values range from 2 to 32.
- **Minimum data region size—**Specifies the minimum data region size. Allowed values range from 64 bytes to 1 MB and must be a power of two.
- **Number of instruction regions**—Specifies the number of instruction regions to allocate. Allowed values range from 2 to 32.
- **Minimum instruction region size**—Specifies the minimum instruction region size. Allowed values range from 64 bytes to 1 MB and must be a power of two.

Note: The maximum region size is the size of the Nios II instruction and data addresses automatically determined when the Nios II system is generated in Qsys. Maximum region size is based on the address range of slaves connected to the Nios II instruction and data masters.

For information about the MPU, refer to the *Programming Model* chapter of the *Nios II Processor Reference Handbook*.

For specifics on the Nios II/f core, refer to the *Nios II Core Implementation Details* chapter of the *Nios II Processor Reference Handbook*.

Related Information

- **Programming Model** on page 3-1
- **Core Implementation Details** on page 5-1

JTAG Debug Module Tab

The **JTAG Debug Module** tab presents settings for configuring the JTAG debug module on the Nios II processor. You can select the debug features appropriate for your target application.

Table 4-5: JTAG Debug Module Tab Parameters

Name	Description
Select a Debugging Level	
Debug level	Refer to the "Debug Level Settings" section.
Include debugreq and debugack Signals	Refer to the "Debug Signals" section.
Break Vector	
Break vector memory	Refer to the "Break Vector" section.
Break vector offset	
Break vector	
Advanced Debug Settings	
OCI Onchip Trace	Refer to "Advanced Debug Settings" section.
Automatically generate internal 2x clock signal	

Soft processor cores such as the Nios II processor offer unique debug capabilities beyond the features of traditional fixed processors. The soft nature of the Nios II processor allows you to debug a system in development using a full-featured debug core, and later remove the debug features to conserve logic resources. For the release version of a product, you might choose to reduce the JTAG debug module functionality, or remove it altogether.

Table 4-6: Debug Configuration Features

Feature	Description
JTAG Target Connection	Connects to the processor through the standard JTAG pins on the Altera FPGA. This connection provides the basic capabilities to start and stop the processor, and examine/edit registers and memory.
Download Software	Downloads executable code to the processor's memory via the JTAG connection.
Software Breakpoints	Sets a breakpoint on instructions residing in RAM.
Hardware Breakpoints	Sets a breakpoint on instructions residing in nonvolatile memory, such as flash memory.
Data Triggers	Triggers based on address value, data value, or read or write cycle. You can use a trigger to halt the processor on specific events or conditions, or to activate other events, such as starting execution trace, or sending a trigger signal to an external logic analyzer. Two data triggers can be combined to form a trigger that activates on a range of data or addresses.
Instruction Trace	Captures the sequence of instructions executing on the processor in real time.
Data Trace	Captures the addresses and data associated with read and write operations executed by the processor in real time.
On-Chip Trace	Stores trace data in on-chip memory.

Feature	Description
Off-Chip Trace	Stores trace data in an external debug probe. Off-chip trace instantiates a PLL inside the Nios II core. Off-chip trace requires a debug probe from Imagination Technologies or Lauterbach GmbH.

The following sections describe the configuration settings available.

Related Information

- **Advanced Debug Settings** on page 4-15
- **Break Vector** on page 4-15
- **Debug Signals** on page 4-15
- **Debug Level Settings** on page 4-14

Debug Level Settings

The following debug levels are available in the **JTAG Debug Module** tab:

- No Debugger
- Level 1
- Level 2
- Level 3
- Level 4

The table is a detailed list of the characteristics of each debug level. Different levels consume different amounts of on-chip resources. Certain Nios II cores have restricted debug options, and certain options require debug tools provided by Imagination Technologies, LLC or Lauterbach GmbH.

Table 4-7: JTAG Debug Module Levels

Debug Feature	No Debug	Level 1	Level 2	Level 3	Level 4[37]
Logic Usage	0	300—400 LEs	800—900 LEs	2,400—2,700 LEs	3,100—3,700 LEs
On-Chip Memory Usage	0	Two M4Ks	Two M4Ks	Four M4Ks	Four M4Ks
External I/O Pins Required[38]	0	0	0	0	20
JTAG Target Connection	No	Yes	Yes	Yes	Yes
Download Software	No	Yes	Yes	Yes	Yes
Software Breakpoints	None	Unlimited	Unlimited	Unlimited	Unlimited
Hardware Execution Breakpoints	0	None	2	2	4
Data Triggers	0	None	2	2	4
On-Chip Trace	0	None	None	Up to 64-KB frames [39]	Up to 64-KB frames

[37] Level 4 requires the purchase of a software upgrade from Imagination Technologies or Lauterbach.
[38] Not including the dedicated JTAG pins on the Altera FPGA.
[39] An additional license from Imagination Technologies is required to use more than 16 frames.

Debug Feature	No Debug	Level 1	Level 2	Level 3	Level 4[37]
Off-Chip Trace [40]	0	None	None	None	128-KB frames

For information about debug features available from these third parties, search for "Nios II" on the Imagination Technologies website and the Lauterbach GmbH website.

Related Information

- **Lauterbach GmbH**
- **Imagination Technologies, LLC**

Debug Signals

The **Include debugreq and debugack signals** debug signals setting provides the following functionality. When on, the Nios II processor includes debug request and acknowledge signals. These signals let another device temporarily suspend the Nios II processor for debug purposes. The signals are exported to the top level of your Qsys system.

For more information about the debug signals, refer to the *Processor Architecture* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Processor Architecture on page 2-1

Break Vector

When the Nios II processor contains a JTAG debug module, Qsys determines a break vector (break address). **Break vector memory** is always the processor core you are configuring. **Break vector offset** is fixed at `0x20`. Qsys calculates the physical address of the break vector from the memory module's base address and the offset.

When the Nios II processor does not contain a JTAG debug module, you can edit the break vector parameters in the manner described in General Exception Vector" section.

Related Information

General Exception Vector on page 4-4

Advanced Debug Settings

Debug levels 3 and 4 support trace data collection into an on-chip memory buffer. You can set the on-chip trace buffer size to sizes from 128 to 64K trace frames, using **OCI Onchip Trace**. Larger buffer sizes consume more on-chip M4K RAM blocks. Every M4K RAM block can store up to 128 trace frames.

Note: The Nios II MMU does not support the JTAG debug module trace.

Debug level 4 also supports manual 2X clock signal specification. If you want to use a specific 2X clock signal in your FPGA design, turn off **Automatically generate internal 2x clock signal** and drive a 2X clock signal into your system manually.

[37] Level 4 requires the purchase of a software upgrade from Imagination Technologies or Lauterbach.
[40] Off-chip trace requires the purchase of additional hardware from Imagination Technologies or Lauterbach.

For more information about trace frames, refer to the *Processor Architecture* chapter of the *Nios II Processor Reference Handbook*.

Related Information

Processor Architecture on page 2-1

Custom Instruction Tab

In Qsys, custom instructions are components in your design that you manually connect to the processor in the Qsys **System Contents** tab. Existing custom instruction components are available on the **Component Library** tab under **Custom Instruction Modules**. Thus, the **Custom Instruction** tab in the Nios II Processor parameter editor is not used in Qsys.

To create your own custom instruction using the component editor, click **New Component** on the File menu in Qsys. After finishing in the component editor, the new instruction appears on the **Component Library** tab under **Custom Instruction Modules** in Qsys.

Note: All signals in Nios II custom instructions must have the **Custom Instruction Slave** interface type.

To guarantee the component editor automatically selects the **Custom Instruction Slave** interface type for your signals correctly during import, begin your signal names with the prefix `ncs_`. This prefix allows the component editor to determine the connection point type: a Nios II custom instruction slave. For example, if a custom instruction component has two data signals plus clock, reset, and result signals, an appropriate set of signal names is `ncs_dataa`, `ncs_datab`, `ncs_clk`, `ncs_reset`, and `ncs_result`.

A complete discussion of the hardware and software design process for custom instructions is beyond the scope of this chapter.

For full details on the topic of custom instructions, including working example designs, refer to the *Nios II Custom Instruction User Guide*.

Related Information

Nios II Custom Instruction User Guide

Altera-Provided Custom Instructions

The following sections describe the custom instructions Altera provides.

Note: The Endian Converter Custom Instruction and Interrupt Vector Custom Instruction are not available in Qsys.

For information about converting SOPC Builder designs to Qsys, refer to the *SOPC Builder to Qsys Migration Guidelines*.

Related Information

SOPC Builder to Qsys Migration Guidelines

Floating Point Hardware 2 Custom Instruction

The Nios II processor offers a set of optional predefined custom instructions that implement floating-point arithmetic operations. You can include these custom instructions to support computation-intensive floating-point applications.

The Floating Point Hardware 2 Custom Instruction is a high performance component with predefined custom instructions that implement single-precision floating-point operations. This component offers improved performance with lower cycle counts for addition, subtraction, multiplication and division, and

also supports floating-point operations such as square root, comparison, minimum/maximum, negate/absolute, and conversion.

The Floating Point Hardware 2 component is composed of two custom instructions:

- Combinational custom instruction—Implements the minimum, maximum, compare, negate, and absolute operations.
- Multi-cycle custom instruction—Implements the add, substract, multiply, divide, square root, and convert operations.

The component has two slaves, one slave for the combinatorial custom instruction and the other slave for the multi-cycle custom instruction.

The opcode extensions for the Floating Point Hardware 2 custom instructions are 224 through 255. Refer to the Floating Point Custom Instruction 2 Operation Summary table in the "Floating Point Custom Instruction 2 Component" section in the *Processor Architecture* chapter for details.

To add the Floating Point Hardware 2 custom instruction to the Nios II processor in Qsys, select **Floating Point Hardware 2** under **Embedded Processors** in the **Component Library** tab. Connect the two slave interfaces to the Nios II custom instruction master.

Floating-Point Hardware Custom Instruction

Floating-Point Hardware Custom Instruction

The Nios II processor offers a set of optional predefined custom instructions that implement floating-point arithmetic operations. You can include these custom instructions to support computation-intensive floating-point applications.

The basic set of floating-point custom instructions includes single precision (32-bit) floating-point addition, subtraction, and multiplication. Floating-point division is available as an extension to the basic instruction set. The best choice for your hardware design depends on a balance among floating-point usage, hardware resource usage, and performance.

If the target device includes on-chip multiplier blocks, the floating-point custom instructions incorporate them as needed. If there are no on-chip multiplier blocks, the floating-point custom instructions are entirely based on general-purpose logic elements.

Note: The opcode extensions for the floating-point custom instructions are 252 through 255 (0xFC through 0xFF). These opcode extensions cannot be modified.

To add the floating-point custom instructions to the Nios II processor in Qsys, select **Floating Point Hardware** under **Custom Instruction Modules** on the **Component Library** tab, and click **Add**. By default, Qsys includes floating-point addition, subtraction, and multiplication, but omit the more resource intensive floating-point division. The **Floating Point Hardware** parameter editor appears, giving you the option to include the floating-point division hardware.

Table 4-8: Floating Point Hardware Parameters

Name	Values	Description
Use floating point division hardware	On/Off	Specifies inclusion of floating-point division hardware.

Turn on **Use floating point division hardware** to include floating-point division hardware. The floating-point division hardware requires more resources than the other instructions, so you might wish to omit it if your application does not make heavy use of floating-point division.

Click **Finish** to add the floating-point custom instructions to the Nios II processor.

For more information about the floating-point custom instructions, refer to the *Processor Architecture* chapter of the *Nios II Processor Reference Handbook*.

Processor Architecture on page 2-1

Bitswap Custom Instruction

The Nios II processor core offers a bitswap custom instruction to reduce the time spent performing bit reversal operations.

To add the bitswap custom instruction to the Nios II processor in Qsys, select **Bitswap** under **Custom Instruction Modules** on the **Component Library** tab, and click **Add**.

The bitswap custom instruction reverses a 32-bit value in a single clock cycle. To perform the equivalent operation in software requires many mask and shift operations.

For details about integrating the bitswap custom instruction into your own algorithm, refer to the *Nios II Custom Instruction User Guide*.

The Quartus Prime IP File

The Quartus® Prime IP file (**.qip**) is a file generated by the MegaWizard™ Plug-In Manager, that contains information about a generated IP core. You are prompted to add this **.qip** file to the current project at the time of Quartus Prime file generation. In most cases, the **.qip** file contains all of the necessary assignments and information required to process the core or system in the Quartus Prime compiler. Generally, a single **.qip** file is generated for each IP core and for each system. However, some complex components generate a separate **.qip** file, so the system **.qip** file references the component **.qip** file.

Document Revision History

Table 4-9: Document Revision History

Date	Version	Changes
April 2015	2015.04.02	Maintenance release.
February 2014	13.1.0	• Added information about the Floating Point Custom Instruction 2 Component • Added information about ECC support. • Removed references to SOPC Builder.
May 2011	11.0.0	• Revised the entire chapter for the new Qsys system integration tool. • Replaced GUI screen shots with parameter tables. • Incorporated interrupt vector custom instruction information from the *Processor Architecture* chapter.

Date	Version	Changes
December 2010	10.1.0	Maintenance release.
July 2010	10.0.0	Maintenance release.
November 2009	9.1.0	• Added external interrupt controller interface information. • Added shadow register set information.
March 2009	9.0.0	Maintenance release.
November 2008	8.1.0	• Added `debugreq` and `debugack` signal options to Advanced Features tab. • Added cpuid manual override options to Advanced Features tab.
May 2008	8.0.0	• Added MMU options to Nios II Core and Advanced Features tabs. • Added exception handling options Advanced Features tab.
October 2007	7.2.0	Changed title to match other Altera documentation.
May 2007	7.1.0	• Revised to reflect new MegaWizard interface. • Added Endian Converter Custom Instruction and Bitswap Custom Instruction section. • Added table of contents to Introduction section. • Added Referenced Documents section.
March 2007	7.0.0	Maintenance release.
November 2006	6.1.0	• Add section on interrupt vector custom instruction. • Add section on system-dependent Nios II processor settings.
May 2006	6.0.0	• Added details on floating-point custom instructions. • Added section on Advanced Features tab.
October 2005	5.1.0	Maintenance release.
May 2005	5.0.0	• Updates to reflect new GUI options in Nios II processor version 5.0. • New details in “Caches and Tightly-Coupled Memory” section.
September 2004	1.1	• Updates to reflect new GUI options in Nios II processor version 1.1. • New details in section “Multiply and Divide Settings.”
May 2004	1.0	Initial release.

Core Implementation Details 5

Preliminary support—The core is verified with preliminary timing models for this device family. The core meets all functional requirements, but might still be undergoing timing analysis for the device family. It can be used in production designs with caution.

Final support—The core is verified with final timing models for this device family. The core meets all functional and timing requirements for the device family and can be used in production designs.

Nios II/f Core

The Nios II/f fast core is designed for high execution performance. Performance is gained at the expense of core size. The base Nios II/f core, without the memory management unit (MMU) or memory protection unit (MPU), is approximately 25% larger than the Nios II/s core. FPGA designed the Nios II/f core with the following design goals in mind:

The Nios II/f fast core is designed for high execution performance. Performance is gained at the expense of core size. FPGA designed the Nios II/f core with the following design goals in mind:

- Maximize the instructions-per-cycle execution efficiency
- Optimize interrupt latency
- Maximize f_{MAX} performance of the processor core

The resulting core is optimal for performance-critical applications, as well as for applications with large amounts of code and data, such as systems running a full-featured operating system.

Overview

The Nios II/f core:

- Has separate optional instruction and data caches
- Provides optional MMU to support operating systems that require an MMU
- Provides optional MPU to support operating systems and runtime environments that desire memory protection but do not need virtual memory management
- Can access up to 2 GB of external address space when no MMU is present and 4 GB when the MMU is present
- Supports optional external interrupt controller (EIC) interface to provide customizable interrupt prioritization
- Supports optional shadow register sets to improve interrupt latency
- Supports optional tightly-coupled memory for instructions and data
- Employs a 6-stage pipeline to achieve maximum DMIPS/MHz
- Performs dynamic branch prediction
- Provides optional hardware multiply, divide, and shift options to improve arithmetic performance
- Supports the addition of custom instructions
- Optional ECC support for internal RAM blocks (instruction cache, MMU TLB, and register file)
- Supports the JTAG debug module
- Supports optional JTAG debug module enhancements, including hardware breakpoints and real-time trace

The following sections discuss the noteworthy details of the Nios II/f core implementation. This document does not discuss low-level design issues or implementation details that do not affect hardware or software designers.

- Has separate optional instruction and data caches
- Provides optional MMU to support operating systems that require an MMU
- Provides optional MPU to support operating systems and runtime environments that desire memory protection but do not need virtual memory management
- Can access up to 4 GB of external address space when bit31 is not enabled
- Supports optional external interrupt controller (EIC) interface to provide customizable interrupt prioritization
- Supports optional shadow register sets to improve interrupt latency
- Supports optional tightly-coupled memory for instructions and data

- Employs a 6-stage pipeline to achieve maximum DMIPS/MHz
- Performs dynamic or static branch prediction
- Provides optional hardware multiply, divide, and shift options to improve arithmetic performance
- Supports the addition of custom instructions
- Optional ECC support for internal RAM blocks (data cache, data cache victim buffer RAM, instruction and data tightly-coupled memories, instruction cache, MMU TLB, and register file)
- Supports the JTAG debug module
- Supports optional JTAG debug module enhancements, including hardware breakpoints and real-time trace

The following sections discuss the noteworthy details of the Nios II/f core implementation. This document does not discuss low-level design issues or implementation details that do not affect hardware or software designers.

Arithmetic Logic Unit

The Nios II/f core provides several arithmetic logic unit (ALU) options to improve the performance of multiply, divide, and shift operations.

Multiply and Divide Performance

The Nios II/f core provides the following hardware multiplier options:

- DSP Block—Includes DSP block multipliers available on the target device. This option is available only on FPGAs that have DSP Blocks.
- Embedded Multipliers—Includes dedicated embedded multipliers available on the target device. This option is available only on FPGAs that have embedded multipliers.
- Logic Elements—Includes hardware multipliers built from logic element (LE) resources.
- None—Does not include multiply hardware. In this case, multiply operations are emulated in software.

The Nios II/f core also provides a hardware divide option that includes LE-based divide circuitry in the ALU.

Including an ALU option improves the performance of one or more arithmetic instructions.

Note: The performance of the embedded multipliers differ, depending on the target FPGA family.

Table 5-3: Hardware Multiply and Divide Details for the Nios II/f Core

ALU Option	Hardware Details	Cycles per Instruction	Result Latency Cycles	Supported Instructions
No hardware multiply or divide	Multiply and divide instructions generate an exception	–	–	None
Logic elements	ALU includes 32 x 4-bit multiplier	11	+2	`mul`, `muli`
DSP block on Stratix III families	ALU includes 32 x 32-bit multiplier	1	+2	`mul`, `muli`, `mulxss`, `mulxsu`, `mulxuu`
Embedded multipliers on Cyclone III families	ALU includes 32 x 16-bit multiplier	5	+2	`mul`, `muli`

ALU Option	Hardware Details	Cycles per Instruction	Result Latency Cycles	Supported Instructions
Hardware divide	ALU includes multicycle divide circuit	4 – 66	+2	`div`, `divu`

The Nios II/f core provides the following hardware multiplier options:

- DSP Block—Includes DSP block multipliers available on the target device. This option is available only on FPGAs that have a hardware multiplier that supports 32-bit multiplication.
- Embedded Multipliers—Includes dedicated embedded multipliers available on the target device. This option is available only on FPGAs that have embedded multipliers.
- Logic Elements—Includes hardware multipliers built from logic element (LE) resources.
- None—Does not include multiply hardware. In this case, multiply operations are emulated in software.

The Nios II/f core also provides a hardware divide option that includes LE-based divide circuitry in the ALU.

Including an ALU option improves the performance of one or more arithmetic instructions.

Note: The performance of the embedded multipliers differ, depending on the target FPGA family.

Table 5-4: Hardware Multiply and Divide Details for the Nios II/f Core

ALU Option	Hardware Details	Cycles per Instruction	Result Latency Cycles	Supported Instructions
No hardware multiply or divide	Multiply and divide instructions generate an exception	–	–	None
Logic elements	ALU includes 32 x 4-bit multiplier	11	+2	`mul`, `muli`
32-bit multiplier	ALU includes 32 x 32-bit multiplier	1	+2	`mul`, `muli`, `mulxss`, `mulxsu`, `mulxuu`
16-bit multiplier	ALU includes 3 16 x 16-bit multiplier	1	+2	`mul`, `muli`
16-bit multiplier	ALU includes 4 16 x 16-bit multiplier	2	+2	`mul`, `muli`, `mulxss`, `mulxsu`, `mulxuu`
Hardware divide	ALU includes SRT Radix-2 divide circuit	35	+2	`div`, `divu`

The cycles per instruction value determines the maximum rate at which the ALU can dispatch instructions and produce each result. The latency value determines when the result becomes available. If there is no data dependency between the results and operands for back-to-back instructions, then the latency does not affect throughput. However, if an instruction depends on the result of an earlier instruction, then the processor stalls through any result latency cycles until the result is ready.

In the following code example, a multiply operation (with 1 instruction cycle and 2 result latency cycles) is followed immediately by an add operation that uses the result of the multiply. On the Nios II/f core, the `addi` instruction, like most ALU instructions, executes in a single cycle. However, in this code example,

execution of the `addi` instruction is delayed by two additional cycles until the multiply operation completes.

```
mul r1, r2, r3        ; r1 = r2 * r3
addi r1, r1, 100      ; r1 = r1 + 100 (Depends on result of mul)
```

In contrast, the following code does not stall the processor.

```
mul r1, r2, r3        ; r1 = r2 * r3
or r5, r5, r6         ; No dependency on previous results
or r7, r7, r8         ; No dependency on previous results
addi r1, r1, 100      ; r1 = r1 + 100 (Depends on result of mul)
```

Shift and Rotate Performance

The performance of shift operations depends on the hardware multiply option. When a hardware multiplier is present, the ALU achieves shift and rotate operations in three or four clock cycles. Otherwise, the ALU includes dedicated shift circuitry that achieves one-bit-per-cycle shift and rotate performance.

Refer to the "Instruction Execution Performance for Nios II/f Core" table in the "Instruction Performance" section for details.

Related Information

Instruction Performance on page 5-12

Memory Access

The Nios II/f core provides optional instruction and data caches. The cache size for each is user-definable, between 512 bytes and 64 KB.

The memory address width in the Nios II/f core depends on whether the optional MMU is present. Without an MMU, the Nios II/f core supports the bit-31 cache bypass method for accessing I/O on the data master port. Therefore addresses are 31 bits wide, reserving bit 31 for the cache bypass function. With an MMU, cache bypass is a function of the memory partition and the contents of the translation lookaside buffer (TLB). Therefore bit-31 cache bypass is disabled, and 32 address bits are available to address memory.

Instruction and Data Master Ports

The instruction master port is a pipelined Memory-Mapped (-MM) master port. If the core includes data cache with a line size greater than four bytes, then the data master port is a pipelined -MM master port. Otherwise, the data master port is not pipelined.

The instruction master port is a pipelined Memory-Mapped (-MM) master port. The core also includes a data cache with a fixed 32-byte line size, making he data master port a pipelined -MM master port.

The instruction and data master ports on the Nios II/f core are optional. A master port can be excluded, as long as the core includes at least one tightly-coupled memory to take the place of the missing master port.

Note: Although the processor can operate entirely out of tightly-coupled memory without the need for -MM instruction or data masters, software debug is not possible when either the -MM instruction or data master is omitted.

Support for pipelined -MM transfers minimizes the impact of synchronous memory with pipeline latency. The pipelined instruction and data master ports can issue successive read requests before prior requests complete.

Instruction and Data Caches

This section first describes the similar characteristics of the instruction and data cache memories, and then describes the differences.

Both the instruction and data cache addresses are divided into fields based on whether or not an MMU is present in your system.

Table 5-5: Cache Byte Address Fields

Bit Fields

											offset				

Instruction Cache

The instruction cache memory has the following characteristics:

- Direct-mapped cache implementation.
- 32 bytes (8 words) per cache line.
- The instruction master port reads an entire cache line at a time from memory, and issues one read per clock cycle.
- Critical word first.
- Virtually-indexed, physically-tagged, when MMU present.

The size of the tag field depends on the size of the cache memory and the physical address size. The size of the line field depends only on the size of the cache memory. The offset field is always five bits (i.e., a 32-byte line). The maximum instruction byte address size is 31 bits in systems without an MMU present. In

systems with an MMU, the maximum instruction byte address size is 32 bits and the tag field always includes all the bits of the physical frame number (PFN).

The instruction cache is optional. However, excluding instruction cache from the Nios II/f core requires that the core include at least one tightly-coupled instruction memory.

Data Cache

The data cache memory has the following characteristics:

- Direct-mapped cache implementation
- Configurable line size of 4, 16, or 32 bytes
- The data master port reads an entire cache line at a time from memory, and issues one read per clock cycle.
- Write-back
- Write-allocate (i.e., on a store instruction, a cache miss allocates the line for that address)
- Virtually-indexed, physically-tagged, when MMU present

The size of the tag field depends on the size of the cache memory and the physical address size. The size of the line field depends only on the size of the cache memory. The size of the offset field depends on the line size. Line sizes of 4, 16, and 32 bytes have offset widths of 2, 4, and 5 bits respectively. The maximum data byte address size is 31 bits in systems without an MMU present. In systems with an MMU, the maximum data byte address size is 32 bits and the tag field always includes all the bits of the PFN.

The data cache is optional. If the data cache is excluded from the core, the data master port can also be excluded.

The Nios II instruction set provides several different instructions to clear the data cache. There are two important questions to answer when determining the instruction to use. Do you need to consider the tag field when looking for a cache match? Do you need to write dirty cache lines back to memory before clearing? Below the table lists the most appropriate instruction to use for each case.

Table 5-8: Data Cache Clearing Instructions

Instruction	Ignore Tag Field	Consider Tag Field
Write Dirty Lines	`flushd`	`flushda`
Do Not Write Dirty Lines	`initd`	`initda`

Note: The 4-byte line data cache implementation substitutes the `flushd` instruction for the `flushda` instruction and triggers an unimplemented instruction exception for the `initda` instruction. The 16-byte and 32-byte line data cache implementations fully support the `flushda` and `initda` instructions.

For more information regarding the Nios II instruction set, refer to the *Instruction Set Reference* chapter of the *Processor Reference Handbook*.

The Nios II/f core implements all the data cache bypass methods.

For information regarding the data cache bypass methods, refer to the *Processor Architecture* chapter of the *Processor Reference Handbook*

Mixing cached and uncached accesses to the same cache line can result in invalid data reads. For example, the following sequence of events causes cache incoherency.

1. The Nios II core writes data to cache, creating a dirty data cache line.
2. The Nios II core reads data from the same address, but bypasses the cache.

Note: Avoid mixing cached and uncached accesses to the same cache line, regardless whether you are reading from or writing to the cache line. If it is necessary to mix cached and uncached data accesses, flush the corresponding line of the data cache after completing the cached accesses and before performing the uncached accesses.

- Direct-mapped cache implementation
- Line size of 32-bytes
- The data master port reads an entire cache line at a time from memory, and issues one read per clock cycle.
- Write-back
- Write-allocate (i.e., on a store instruction, a cache miss allocates the line for that address)
- Virtually-indexed, physically-tagged, when MMU present

The size of the tag field depends on the size of the cache memory and the physical address size. The size of the line field depends only on the size of the cache memory. The size of the offset field depends on the line size. Line sizes of 32 bytes have offset widths of 5-bits. The maximum data byte address size is 31 bits in systems without an MMU present. In systems with an MMU, the maximum data byte address size is 32 bits and the tag field always includes all the bits of the PFN.

The data cache is optional. If the data cache is excluded from the core, the data master port can also be excluded.

The Nios II instruction set provides several different instructions to clear the data cache. There are two important questions to answer when determining the instruction to use. Do you need to consider the tag field when looking for a cache match? Do you need to write dirty cache lines back to memory before clearing? Below the table lists the most appropriate instruction to use for each case.

Table 5-9: Data Cache Clearing Instructions

Instruction	Ignore Tag Field	Consider Tag Field
Write Dirty Lines	`flushd`	`flushda`
Do Not Write Dirty Lines	`initd`	`initda`

For more information regarding the Nios II instruction set, refer to the *Instruction Set Reference* chapter of the *Processor Reference Handbook*.

The Nios II/f core implements all the data cache bypass methods.

For information regarding the data cache bypass methods, refer to the *Processor Architecture* chapter of the *Processor Reference Handbook*

Mixing cached and uncached accesses to the same cache line can result in invalid data reads. For example, the following sequence of events causes cache incoherency.

1. The Nios II core writes data to cache, creating a dirty data cache line.
2. The Nios II core reads data from the same address, but bypasses the cache.

Note: Avoid mixing cached and uncached accesses to the same cache line, regardless whether you are reading from or writing to the cache line. If it is necessary to mix cached and uncached data accesses, flush the corresponding line of the data cache after completing the cached accesses and before performing the uncached accesses.

Bursting

When the data cache is enabled, you can enable bursting on the data master port. Consult the documentation for memory devices connected to the data master port to determine whether bursting can improve performance.

Tightly-Coupled Memory

The Nios II/f core provides optional tightly-coupled memory interfaces for both instructions and data. A Nios II/f core can use up to four each of instruction and data tightly-coupled memories. When a tightly-coupled memory interface is enabled, the Nios II core includes an additional memory interface master port. Each tightly-coupled memory interface must connect directly to exactly one memory slave port.

When tightly-coupled memory is present, the Nios II core decodes addresses internally to determine if requested instructions or data reside in tightly-coupled memory. If the address resides in tightly-coupled memory, the Nios II core fetches the instruction or data through the tightly-coupled memory interface. Software accesses tightly-coupled memory with the usual load and store instructions, such as `ldw` or `ldwio`.

Accessing tightly-coupled memory bypasses cache memory. The processor core functions as if cache were not present for the address span of the tightly-coupled memory. Instructions for managing cache, such as `initd` and `flushd`, do not affect the tightly-coupled memory, even if the instruction specifies an address in tightly-coupled memory.

When the MMU is present, tightly-coupled memories are always mapped into the kernel partition and can only be accessed in supervisor mode.

Memory Management Unit

The Nios II/f core provides options to improve the performance of the Nios II MMU.

For information about the MMU architecture, refer to the *Programming Model* chapter of the *Processor Reference Handbook*.

Related Information

Programming Model on page 3-1

Micro Translation Lookaside Buffers

The translation lookaside buffer (TLB) consists of one main TLB stored in on-chip RAM and two separate micro TLBs (µTLB) for instructions µITLB) and data (µDTLB) stored in LE-based registers.

The TLBs have a configurable number of entries and are fully associative. The default configuration has 6 µDTLB entries and 4 µITLB entries. The hardware chooses the least-recently used µTLB entry when loading a new entry.

The µTLBs are not visible to software. They act as an inclusive cache of the main TLB. The processor firsts look for a hit in the µTLB. If it misses, it then looks for a hit in the main TLB. If the main TLB misses, the processor takes an exception. If the main TLB hits, the TLB entry is copied into the µTLB for future accesses.

The hardware automatically flushes the µTLB on each TLB write operation and on a `wrctl` to the `tlbmisc` register in case the process identifier (PID) has changed.

Memory Protection Unit

The Nios II/f core provides options to improve the performance of the Nios II MPU.

For information about the MPU architecture, refer to the *Programming Model* chapter of the *Processor Reference Handbook*.

Programming Model on page 3-1

Execution Pipeline

This section provides an overview of the pipeline behavior for the benefit of performance-critical applications. Designers can use this information to minimize unnecessary processor stalling. Most application programmers never need to analyze the performance of individual instructions.

The Nios II/f core employs a 6-stage pipeline.

Table 5-10: Implementation Pipeline Stages for Nios II/f Core

Stage Letter	Stage Name
F	Fetch
D	Decode
E	Execute
M	Memory
A	Align
W	Writeback

Up to one instruction is dispatched or retired per cycle. Instructions are dispatched and retired in order. Dynamic branch prediction is implemented using a 2-bit branch history table. The pipeline stalls for the following conditions:

- Multi-cycle instructions
- -MM instruction master port read accesses
- -MM data master port read/write accesses
- Data dependencies on long latency instructions (for example: load, multiply, shift).

Pipeline Stalls

The pipeline is set up so that if a stage stalls, no new values enter that stage or any earlier stages. No "catching up" of pipeline stages is allowed, even if a pipeline stage is empty.

Only the A-stage and D-stage are allowed to create stalls.

The A-stage stall occurs if any of the following conditions occurs:

- An A-stage memory instruction is waiting for -MM data master requests to complete. Typically this happens when a load or store misses in the data cache, or a `flushd` instruction needs to write back a dirty line.
- An A-stage shift/rotate instruction is still performing its operation. This only occurs with the multicycle shift circuitry (i.e., when the hardware multiplier is not available).
- An A-stage divide instruction is still performing its operation. This only occurs when the optional divide circuitry is available.
- An A-stage multicycle custom instruction is asserting its stall signal. This only occurs if the design includes multicycle custom instructions.

The D-stage stall occurs if an instruction is trying to use the result of a late result instruction too early and no M-stage pipeline flush is active. The late result instructions are loads, shifts, rotates, `rdctl`, multiplies (if hardware multiply is supported), divides (if hardware divide is supported), and multicycle custom instructions (if present).

Branch Prediction

The Nios II/f core performs dynamic branch prediction to minimize the cycle penalty associated with taken branches.

The Nios II/f core performs dynamic and static branch predictions to minimize the cycle penalty associated with taken branches.

Instruction Performance

All instructions take one or more cycles to execute. Some instructions have other penalties associated with their execution. Late result instructions have two cycles placed between them and an instruction that uses their result. Instructions that flush the pipeline cause up to three instructions after them to be cancelled. This creates a three-cycle penalty and an execution time of four cycles. Instructions that require -MM transfers are stalled until any required -MM transfers (up to one write and one read) are completed.

Table 5-11: Instruction Execution Performance for Nios II/f Core 4byte/line data cache

Instruction	Cycles	Penalties
Normal ALU instructions (e.g., add, cmplt)	1	
Combinatorial custom instructions	1	
Multicycle custom instructions	> 1	Late result
Branch (correctly predicted, taken)	2	
Branch (correctly predicted, not taken)	1	
Branch (mispredicted)	4	Pipeline flush
`trap`, `break`, `eret`, `bret`, `flushp`, `wrctl`, `wrprs`; illegal and unimplemented instructions	4 or 5	Pipeline flush
`call`, `jmpi`, `rdprs`	2	
`jmp`, `ret`, `callr`	3	
`rdctl`	1	Late result
`load` (without -MM transfer)	1	Late result

Instruction	Cycles	Penalties
`load` (with -MM transfer)	> 1	Late result
`store` (without -MM transfer)	1	
`store` (with -MM transfer)	> 1	
`flushd`, `flushda` (without -MM transfer)	2	
`flushd`, `flushda` (with -MM transfer)	> 2	
`initd`, `initda`	2	
`flushi`, `initi`	4	
Multiply		Late result
Divide		Late result
Shift/rotate (with hardware multiply using embedded multipliers)	1	Late result
Shift/rotate (with hardware multiply using LE-based multipliers)	2	Late result
Shift/rotate (without hardware multiply present)	1 to 32	Late result
All other instructions	1	

For Multiply and Divide, the number of cycles depends on the hardware multiply or divide option. Refer to "Arithmetic Logic Unit" and "Instruction and Data Caches" s for details.

In the default Nios II/f configuration, instructions `trap, break, eret, bret, flushp, wrctl, wrprs` require four clock cycles. If any of the following options are present, they require five clock cycles:

- MMU
- MPU
- Division exception
- Misaligned load/store address exception
- EIC port
- Shadow register sets

Exception Handling

The Nios II/f core supports the following exception types:

- Hardware interrupts
- Software trap
- Illegal instruction
- Unimplemented instruction
- Supervisor-only instruction (MMU or MPU only)
- Supervisor-only instruction address (MMU or MPU only)
- Supervisor-only data address (MMU or MPU only)
- Misaligned data address

- Misaligned destination address
- Division error
- Fast translation lookaside buffer (TLB) miss (MMU only)
- Double TLB miss (MMU only)
- TLB permission violation (MMU only)
- MPU region violation (MPU only)

- Hardware interrupts
- Software trap
- Illegal instruction
- Unimplemented instruction
- Supervisor-only instruction (MMU or MPU only)
- Supervisor-only instruction address (MMU or MPU only)
- Supervisor-only data address (MMU or MPU only)
- Misaligned data address
- Misaligned destination address
- Division error
- Error-correcting code (ECC)
- Fast translation lookaside buffer (TLB) miss (MMU only)
- Double TLB miss (MMU only)
- TLB permission violation (MMU only)
- MPU region violation (MPU only)

External Interrupt Controller Interface

The EIC interface enables you to speed up interrupt handling in a complex system by adding a custom interrupt controller.

The EIC interface is an -ST sink with the following input signals:

- `eic_port_valid`
- `eic_port_data`

Signals are rising-edge triggered, and synchronized with the Nios II clock input.

The EIC interface presents the following signals to the processor through the `eic_port_data` signal:

- Requested handler address (RHA)—The 32-bit address of the interrupt handler associated with the requested interrupt.
- Requested register set (RRS)—The six-bit number of the register set associated with the requested interrupt.
- Requested interrupt level (RIL)—The six-bit interrupt level. If RIL is 0, no interrupt is requested.
- Requested nonmaskable interrupt (RNMI) flag—A one-bit flag indicating whether the interrupt is to be treated as nonmaskable.

Table 5-12: eic_port_data Signal

Bit Fields														
44	...													
RHA														
...	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RHA		RRS						RNMI	RIL					

Following -ST protocol requirements, the EIC interface samples `eic_port_data` only when `eic_port_valid` is asserted (high). When `eic_port_valid` is not asserted, the processor latches the previous values of RHA, RRS, RIL and RNMI. To present new values on `eic_port_data`, the EIC must transmit a new packet, asserting `eic_port_valid`. An EIC can transmit a new packet once per clock cycle.

For an example of an EIC implementation, refer to the *Vectored Interrupt Controller* chapter in the Embedded Peripherals IP User Guide.

Embedded Peripherals IP User Guide

ECC

The /f core has the option to add ECC support for the following internal RAM blocks.

- Instruction cache
  - ECC errors (1, 2, or 3 bits) that occur in the instruction cache are recoverable; the processor flushes the cache line and reads from external memory instead of correcting the ECC error.
- Register file
  - 1 bit ECC errors are recoverable
  - 2 bit ECC errors are not recoverable and generate ECC exceptions
- MMU TLB
  - 1 bit ECC errors triggered by hardware reads are recoverable
  - 2 bit ECC errors triggered by hardware reads are not recoverable and generate ECC exception.
  - 1 or 2 bit ECC errors triggered by software reads to the TLBMISC register do not trigger an exception, instead, TLBMISC.EE is set to 1. Software must read this field and invalidate/overwrite the TLB entry.

The ECC interface is an -ST source with the output signal `ecc_event_bus`. This interface allows external logic to monitor ECC errors in the processor.

The ecc_event_bus contains the ECC error signals that are driven to 1 even if ECC checking is disabled in the processor (when CONFIG.ECCEN or CONFIG.ECCEXC is 0). The following table describes the ECC error signals.

- Instruction cache
  - ECC errors (1, 2, or 3 bits) that occur in the instruction cache are recoverable; the processor flushes the cache line and reads from external memory instead of correcting the ECC error.
- Register file
  - 1 bit ECC errors are recoverable
  - 2 bit ECC errors are not recoverable and generate ECC exceptions
- MMU TLB
  - 1 bit ECC errors triggered by hardware reads are recoverable
  - 2 bit ECC errors triggered by hardware reads are not recoverable and generate ECC exception.
  - 1 or 2 bit ECC errors triggered by software reads to the TLBMISC register do not trigger an exception, instead, TLBMISC.EE is set to 1. Software must read this field and invalidate/overwrite the TLB entry.
- Data Cache
  - tag RAM—The ECCINJ.DCTAG field is used to inject ECC errors into the tag RAM.
  - data RAM—The ECCINJ.DCDAT field is used to inject ECC errors into the data RAM
- Tightly-Coupled Memories (TCMs)— includes the ECC encoder/decoder logic for each TCM and the TCM master port data width is increased to allow the to read and write the ECC parity bits.The TCM must be a RAM and must store the ECC parity bits along with the data bits.
  - Instruction Tightly-Coupled Memories (ITCM)— supports up to 4 ITCMs
  - Data Tightly-Coupled Memories (DTCM)— supports up to 4 DTCMs

The ECC interface is an -ST source with the output signal ecc_event_bus. This interface allows external logic to monitor ECC errors in the processor.

JTAG Debug Module

The Nios II/f core supports the JTAG debug module to provide a JTAG interface to software debugging tools. The Nios II/f core supports an optional enhanced interface that allows real-time trace data to be routed out of the processor and stored in an external debug probe.

Note: The Nios II MMU does not support the JTAG debug module trace.

Nios II/s Core

The Nios II/s standard core is designed for small core size. On-chip logic and memory resources are conserved at the expense of execution performance. The Nios II/s core uses approximately 20% less logic than the Nios II/f core, but execution performance also drops by roughly 40%. FPGA designed the Nios II/s core with the following design goals in mind:

- Do not cripple performance for the sake of size.
- Remove hardware features that have the highest ratio of resource usage to performance impact.

The resulting core is optimal for cost-sensitive, medium-performance applications. This includes applications with large amounts of code as well as data, such as systems running an operating system in which performance is not the highest priority.

Overview

The Nios II/s core:

- Has an instruction cache, but no data cache
- Can access up to 2 GB of external address space
- Supports optional tightly-coupled memory for instructions
- Employs a 5-stage pipeline
- Performs static branch prediction
- Provides hardware multiply, divide, and shift options to improve arithmetic performance
- Supports the addition of custom instructions
- Supports the JTAG debug module
- Supports optional JTAG debug module enhancements, including hardware breakpoints and real-time trace

The following sections discuss the noteworthy details of the Nios II/s core implementation. This document does not discuss low-level design issues or implementation details that do not affect hardware or software designers.

Arithmetic Logic Unit

The Nios II/s core provides several ALU options to improve the performance of multiply, divide, and shift operations.

Multiply and Divide Performance

The Nios II/s core provides the following hardware multiplier options:

- DSP Block—Includes DSP block multipliers available on the target device. This option is available only on FPGAs that have DSP Blocks.
- Embedded Multipliers—Includes dedicated embedded multipliers available on the target device. This option is available only on FPGAs that have embedded multipliers.
- Logic Elements—Includes hardware multipliers built from logic element (LE) resources.
- None—Does not include multiply hardware. In this case, multiply operations are emulated in software.

The Nios II/s core also provides a hardware divide option that includes LE-based divide circuitry in the ALU.

Including an ALU option improves the performance of one or more arithmetic instructions.

Note: The performance of the embedded multipliers differ, depending on the target FPGA family.

Table 5-15: Hardware Multiply and Divide Details for the Nios II/s Core

ALU Option	Hardware Details	Cycles per instruction	Supported Instructions
No hardware multiply or divide	Multiply and divide instructions generate an exception	–	None
LE-based multiplier	ALU includes 32 x 4-bit multiplier	11	`mul`, `muli`
Embedded multiplier on Stratix III families	ALU includes 32 x 32-bit multiplier	3	`mul`, `muli`, `mulxss`, `mulxsu`, `mulxuu`
Embedded multiplier on Cyclone III families	ALU includes 32 x 16-bit multiplier	5	`mul`, `muli`

ALU Option	Hardware Details	Cycles per instruction	Supported Instructions
Hardware divide	ALU includes multicycle divide circuit	4 – 66	`div`, `divu`

Shift and Rotate Performance

The performance of shift operations depends on the hardware multiply option. When a hardware multiplier is present, the ALU achieves shift and rotate operations in three or four clock cycles. Otherwise, the ALU includes dedicated shift circuitry that achieves one-bit-per-cycle shift and rotate performance.

Refer to the "Instruction Execution Performance for Nios II/s Core" table in the "Instruction Performance" section for details.

Related Information

Instruction Performance on page 5-23

Memory Access

The Nios II/s core provides instruction cache, but no data cache. The instruction cache size is user-definable, between 512 bytes and 64 KB. The Nios II/s core can address up to 2 GB of external memory. The Nios II architecture reserves the most-significant bit of data addresses for the bit-31 cache bypass method. In the Nios II/s core, bit 31 is always zero.

For information regarding data cache bypass methods, refer to the *Processor Architecture* chapter of the *Processor Reference Handbook*.

Related Information

Processor Architecture on page 2-1

Instruction and Data Master Ports

The instruction master port is a pipelined Memory-Mapped (-MM) master port. If the core includes data cache with a line size greater than four bytes, then the data master port is a pipelined -MM master port. Otherwise, the data master port is not pipelined.

The instruction master port is a pipelined Memory-Mapped (-MM) master port. The core also includes a data cache with a fixed 32-byte line size, making he data master port a pipelined -MM master port.

The instruction and data master ports on the Nios II/f core are optional. A master port can be excluded, as long as the core includes at least one tightly-coupled memory to take the place of the missing master port.

Note: Although the processor can operate entirely out of tightly-coupled memory without the need for -MM instruction or data masters, software debug is not possible when either the -MM instruction or data master is omitted.

Support for pipelined -MM transfers minimizes the impact of synchronous memory with pipeline latency. The pipelined instruction and data master ports can issue successive read requests before prior requests complete.

Instruction Cache

The instruction cache for the Nios II/s core is nearly identical to the instruction cache in the Nios II/f core. The instruction cache memory has the following characteristics:

- Direct-mapped cache implementation
- The instruction master port reads an entire cache line at a time from memory, and issues one read per clock cycle.
- Critical word first

Table 5-16: Instruction Byte Address Fields

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
tag													line		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
line											offset				

The size of the tag field depends on the size of the cache memory and the physical address size. The size of the line field depends only on the size of the cache memory. The offset field is always five bits (i.e., a 32-byte line). The maximum instruction byte address size is 31 bits.

The instruction cache is optional. However, excluding instruction cache from the Nios II/s core requires that the core include at least one tightly-coupled instruction memory.

Tightly-Coupled Memory

The Nios II/s core provides optional tightly-coupled memory interfaces for instructions. A Nios II/s core can use up to four tightly-coupled instruction memories. When a tightly-coupled memory interface is enabled, the Nios II core includes an additional memory interface master port. Each tightly-coupled memory interface must connect directly to exactly one memory slave port.

When tightly-coupled memory is present, the Nios II core decodes addresses internally to determine if requested instructions reside in tightly-coupled memory. If the address resides in tightly-coupled memory, the Nios II core fetches the instruction through the tightly-coupled memory interface. Software does not require awareness of whether code resides in tightly-coupled memory or not.

Accessing tightly-coupled memory bypasses cache memory. The processor core functions as if cache were not present for the address span of the tightly-coupled memory. Instructions for managing cache, such as `initi` and `flushi`, do not affect the tightly-coupled memory, even if the instruction specifies an address in tightly-coupled memory.

Execution Pipeline

This section provides an overview of the pipeline behavior for the benefit of performance-critical applications. Designers can use this information to minimize unnecessary processor stalling. Most application programmers never need to analyze the performance of individual instructions.

The Nios II/s core employs a 5-stage pipeline.

Table 5-17: Implementation Pipeline Stages for Nios II/s Core

Stage Letter	Stage Name
F	Fetch
D	Decode
E	Execute

Stage Letter	Stage Name
M	Memory
W	Writeback

Up to one instruction is dispatched or retired per cycle. Instructions are dispatched and retired in-order. Static branch prediction is implemented using the branch offset direction; a negative offset (backward branch) is predicted as taken, and a positive offset (forward branch) is predicted as not taken. The pipeline stalls for the following conditions:

- Multi-cycle instructions (e.g., shift/rotate without hardware multiply)
- -MM instruction master port read accesses
- -MM data master port read/write accesses
- Data dependencies on long latency instructions (for example: load, multiply, shift operations)

Pipeline Stalls

The pipeline is set up so that if a stage stalls, no new values enter that stage or any earlier stages. No "catching up" of pipeline stages is allowed, even if a pipeline stage is empty.

Only the M-stage is allowed to create stalls.

The M-stage stall occurs if any of the following conditions occurs:

- An M-stage load/store instruction is waiting for -MM data master transfer to complete.
- An M-stage shift/rotate instruction is still performing its operation when using the multicycle shift circuitry (i.e., when the hardware multiplier is not available).
- An M-stage shift/rotate/multiply instruction is still performing its operation when using the hardware multiplier (which takes three cycles).
- An M-stage multicycle custom instruction is asserting its stall signal. This only occurs if the design includes multicycle custom instructions.

Branch Prediction

The Nios II/s core performs static branch prediction to minimize the cycle penalty associated with taken branches.

Instruction Performance

All instructions take one or more cycles to execute. Some instructions have other penalties associated with their execution. Instructions that flush the pipeline cause up to three instructions after them to be cancelled. This creates a three-cycle penalty and an execution time of four cycles. Instructions that require an -MM transfer are stalled until the transfer completes.

Table 5-18: Instruction Execution Performance for Nios II/s Core

Instruction	Cycles	Penalties
Normal ALU instructions (e.g., `add`, `cmplt`)	1	
Combinatorial custom instructions	1	

Instruction	Cycles	Penalties
Multicycle custom instructions	> 1	
Branch (correctly predicted taken)	2	
Branch (correctly predicted not taken)	1	
Branch (mispredicted)	4	Pipeline flush
`trap`, `break`, `eret`, `bret`, `flushp`, `wrctl`, unimplemented	4	Pipeline flush
`jmp`, `jmpi`, `ret`, `call`, `callr`	4	Pipeline flush
`rdctl`	1	
`load`, `store`	> 1	
`flushi`, `initi`	4	
Multiply		
Divide		
Shift/rotate (with hardware multiply using embedded multipliers)	3	
Shift/rotate (with hardware multiply using LE-based multipliers)	4	
Shift/rotate (without hardware multiply present)	1 to 32	
All other instructions	1	

Exception Handling

The Nios II/s core supports the following exception types:

- Internal hardware interrupt
- Software trap
- Illegal instruction
- Unimplemented instruction

JTAG Debug Module

The Nios II/s core supports the JTAG debug module to provide a JTAG interface to software debugging tools. The Nios II/s core supports an optional enhanced interface that allows real-time trace data to be routed out of the processor and stored in an external debug probe.

Nios II/e Core

The Nios II/e economy core is designed to achieve the smallest possible core size. FPGA designed the Nios II/e core with a singular design goal: reduce resource utilization any way possible, while still maintaining compatibility with the Nios II instruction set architecture. Hardware resources are conserved at the expense of execution performance. The Nios II/e core is roughly half the size of the Nios II/s core, but the execution performance is substantially lower.

The Nios II/e economy core is designed to achieve the smallest possible core size. FPGA designed the Nios II/e core with a singular design goal: reduce resource utilization any way possible, while still maintaining compatibility with the Nios II instruction set architecture. Hardware resources are conserved at the expense of execution performance.

The resulting core is optimal for cost-sensitive applications as well as applications that require simple control logic.

Overview

The Nios II/e core:

- Executes at most one instruction per six clock cycles
- Can access up to 2 GB of external address space
- Supports the addition of custom instructions
- Supports the JTAG debug module
- Does not provide hardware support for potential unimplemented instructions
- Has no instruction cache or data cache
- Does not perform branch prediction

The following sections discuss the noteworthy details of the Nios II/e core implementation. This document does not discuss low-level design issues, or implementation details that do not affect hardware or software designers.

- Executes at most one instruction per six clock cycles
- Full 32-bit addressing
- Can access up to 4 GB of external address space
- Supports the addition of custom instructions
- Supports the JTAG debug module
- Does not provide hardware support for potential unimplemented instructions
- Has no instruction cache or data cache
- Does not perform branch prediction

The following sections discuss the noteworthy details of the Nios II/e core implementation. This document does not discuss low-level design issues, or implementation details that do not affect hardware or software designers.

Arithmetic Logic Unit

The Nios II/e core does not provide hardware support for any of the potential unimplemented instructions. All unimplemented instructions are emulated in software.

The Nios II/e core employs dedicated shift circuitry to perform shift and rotate operations. The dedicated shift circuitry achieves one-bit-per-cycle shift and rotate operations.

Memory Access

The Nios II/e core does not provide instruction cache or data cache. All memory and peripheral accesses generate an -MM transfer. The Nios II/e core can address up to 2 GB of external memory. The Nios II architecture reserves the most-significant bit of data addresses for the bit-31 cache bypass method. In the Nios II/e core, bit 31 is always zero.

The Nios II/e core does not provide instruction cache or data cache. All memory and peripheral accesses generate an -MM transfer. The Nios II/e core can address up to 4 GB of external memory, full 32-bit addressing.

For information regarding data cache bypass methods, refer to the Processor Architecture chapter of the *Processor Reference Handbook*.

The Nios II/e core does not provide instruction cache or data cache. All memory and peripheral accesses generate an -MM transfer.

Processor Architecture on page 2-1

Instruction Execution Stages

This section provides an overview of the pipeline behavior as a means of estimating assembly execution time. Most application programmers never need to analyze the performance of individual instructions.

Instruction Performance

The Nios II/e core dispatches a single instruction at a time, and the processor waits for an instruction to complete before fetching and dispatching the next instruction. Because each instruction completes before the next instruction is dispatched, branch prediction is not necessary. This greatly simplifies the consideration of processor stalls. Maximum performance is one instruction per six clock cycles. To achieve six cycles, the -MM instruction master port must fetch an instruction in one clock cycle. A stall on the -MM instruction master port directly extends the execution time of the instruction.

Table 5-19: Instruction Execution Performance for Nios II/e Core

Instruction	Cycles
Normal ALU instructions (e.g., `add`, `cmplt`)	6
All branch, `jmp`, `jmpi`, `ret`, `call`, `callr`	6
`trap`, `break`, `eret`, `bret`,`flushp`, `wrctl`, `rdctl`,unimplemented	6
All load word	6 + Duration of -MM read transfer
All load halfword	9 + Duration of -MM read transfer
All load byte	10 + Duration of -MM read transfer
All store	6 + Duration of -MM write transfer
All shift, all rotate	7 to 38

Instruction	Cycles
All other instructions	6
Combinatorial custom instructions	6
Multicycle custom instructions	6

Exception Handling

The Nios II/e core supports the following exception types:

- Internal hardware interrupt
- Software trap
- Illegal instruction
- Unimplemented instruction

JTAG Debug Module

The Nios II/e core supports the JTAG debug module to provide a JTAG interface to software debugging tools. The JTAG debug module on the Nios II/e core does not support hardware breakpoints or trace.

Core Implementation Details Revision History

Table 5-20: Document Revision History

Date	Version	Changes
May 2017	2017.05.08	Updated: • **Core Implementation Details** on page 5-1: Added link to Performance Benchmarks
April 2015	2015.04.02	Obsolete devices removed (Stratix II, Cyclone II).
February 2014	13.1.0	• Added information on ECC support • Removed HardCopy support information • Removed references to SOPC Builder
May 2011	11.0.0	Maintenance release.
December 2010	10.1.0	Maintenance release.
July 2010	10.0.0	• Updated device support nomenclature • Corrected HardCopy support information
November 2009	9.1.0	• Added external interrupt controller interface information. • Added shadow register set information.
March 2009	9.0.0	Maintenance release.
November 2008	8.1.0	Maintenance release.

Date	Version	Changes
May 2008	8.0.0	Added text for MMU and MPU.
October 2007	7.2.0	Added `jmpi` instruction to tables.
May 2007	7.1.0	• Added table of contents to Introduction section. • Added Referenced Documents section.
March 2007	7.0.0	Add preliminary Cyclone III device family support
November 2006	6.1.0	Add preliminary Stratix III device family support
May 2006	6.0.0	Performance for `flushi` and `initi` instructions changes from 1 to 4 cycles for Nios II/s and Nios II/f cores.
October 2005	5.1.0	Maintenance release.
May 2005	5.0.0	Updates to Nios II/f and Nios II/s cores. Added tightly-coupled memory and new data cache options. Corrected cycle counts for shift/rotate operations.
December 2004	1.2	Updates to Multiply and Divide Performance section for Nios II/f and Nios II/s cores.
September 2004	1.1	Updates for Nios II 1.01 release.
May 2004	1.0	Initial release.

Processor Versions 6

2016.10.28

NII51018

Each release of the Embedded Design Suite (EDS) introduces improvements to the processor, the software development tools, or both. This chapter catalogs the history of revisions to the processor; it does not track revisions to development tools, such as the Software Build Tools (SBT).

Improvements to the processor might affect:

- Features of the architecture—An example of an architecture revision is adding instructions to support floating-point arithmetic.
- Implementation of a specific core—An example of a core revision is increasing the maximum possible size of the data cache memory for the /f core.
- Features of the JTAG debug module—An example of a JTAG debug module revision is adding an additional trigger input to the JTAG debug module, allowing it to halt processor execution on a new type of trigger event.

FPGA implements revisions such that code written for an existing core also works on future revisions of the same core.

Nios II Versions Revision History

The number for any version of the processor is determined by the version of the Nios II EDS. For example, in the Nios II EDS version 8.0, all Nios II cores are also version 8.0.

Table 6-1: Processor Revision History

Version	Release Date	Notes
13.1	November 2013	• Added ECC support for internal RAM blocks (instruction cache, MMU TLB, and register file) • Added support for enhanced floating-point custom instructions
11.0	May 2011	No changes.
10.1	December 2010	No changes.
10.0	July 2010	No changes.

Version	Release Date	Notes
9.1	November 2009	• Added optional external interrupt controller interface. • Added optional shadow register sets.
9.0	March 2009	No changes.
8.1	November 2008	No changes.
8.0	May 2008	• Added an optional memory management unit (MMU). • Added an optional memory protection unit (MPU). • Added advanced exception checking. • Added the `initda` instruction.
7.2	October 2007	Added the `jmpi` instruction.
7.1	May 2007	No changes.
7.0	March 2007	No changes.
6.1	November 2006	No changes.
6.0	May 2006	The name Nios II Development Kit describing the software development tools changed to Nios II Embedded Design Suite.
5.1 SP1	January 2006	Bug fix for Nios II/f core.
5.1	October 2005	No changes.
5.0	May 2005	• Changed version nomenclature. FPGA now aligns the processor version with FPGA's Quartus® II software version. • Memory structure enhancements: (1) Added tightly-coupled memory. (2) Made data cache line size configurable. (3) Made cache optional in Nios II/f and Nios II/s cores. • Support for HardCopy® devices.
1.1	December 2004	• Minor enhancements to the architecture: Added `cpuid` control register, and updated the `break` instruction. • Increased user control of multiply and shift hardware in the arithmetic logic unit (ALU) for Nios II/s and Nios II/f cores. • Minor bug fixes.
1.01	September 2004	• Minor bug fixes.
1.0	May2004	Initial release of the processor.

The number for any version of the processor is determined by the version of the Nios II EDS.

Document Version	Changes
2019.04.30	Maintenance release
2015.01.01	Initial release of the processor.

Architecture Revisions

Architecture revisions augment the fundamental capabilities of the Nios II architecture, and affect all Nios II cores. A change in the architecture mandates a revision to all Nios II cores to accommodate the new architectural enhancement. For example, when FPGA adds a new instruction to the instruction set, FPGA consequently must update all Nios II cores to recognize the new instruction.

Table 6-3: Nios II Architecture Revisions

Version	Release Date	Notes
13.1	November 2013	• Added ECC support for internal RAM blocks (instruction cache, MMU TLB, and register file) • Added support for enhanced floating-point custom instructions
11.0	May 2011	No changes.
10.1	December 2010	No changes.
10.0	July 2010	No changes.
9.1	November 2009	• Added optional external interrupt controller interface. • Added optional shadow register sets.
9.0	March 2009	No changes.
8.1	November 2008	No changes.
8.0	May 2008	• Added an optional MMU. • Added an optional MPU. • Added advanced exception checking to detect division errors, illegal instructions, misaligned memory accesses, and provide extra exception information. • Added the `initda` instruction.
7.2	October 2007	Added the `jmpi` instruction.
7.1	May 2007	No changes.
7.0	March 2007	No changes.
6.1	November 2006	No changes.
6.0	May 2006	Added optional `cpu_resetrequest` and `cpu_resettaken` signals to all processor cores.

Version	Release Date	Notes
5.1	October 2005	No changes.
5.0	May 2005	Added the `flushda` instruction.
1.1	December 2004	• Added `cpuid` control register. • Updated `break` instruction specification to accept an immediate argument for use by debugging tools.
1.01	September 2004	No changes.
1.0	May 2004	Initial release of the Nios II processor architecture.

Table 6-4: Nios II Architecture Revisions

Version	Release Date	Notes
14.0	January 2015	Initial release of the processor architecture.

Core Revisions

Core revisions introduce changes to an existing Nios II core. Core revisions most commonly fix identified bugs, or add support for an architecture revision. Not every Nios II core is revised with every release of the Nios II architecture.

Nios II/f Core

Table 6-5: Nios II/f Core Revisions

Version	Release Date	Notes
13.1	November 2013	• Added ECC support for internal RAM blocks (instruction cache, MMU TLB, and register file) • Added support for enhanced floating-point custom instructions
11.0	May 2011	No changes.
10.1	December 2010	No changes.
10.0	July 2010	No changes.
9.1	November 2009	• Added optional external interrupt controller interface. • Added optional shadow register sets.
9.0	March 2009	No changes.
8.1	November 2008	No changes.

Version	Release Date	Notes
8.0	May 2008	• Implemented the optional MMU. • Implemented the optional MPU. • Implemented advanced exception checking. • Implemented the `initda` instruction.
7.2	October 2007	Implemented the `jmpi` instruction.
7.1	May 2007	No changes.
7.0	March 2007	No changes.
6.1	November 2006	No changes.
6.0	May 2006	Cycle count for `flushi` and `initi` instructions changes from 1 to 4 cycles.
5.1 SP1	January 2006	Bug Fix: Back-to-back store instructions can cause memory corruption to the stored data. If the first store is not to the last word of a cache line and the second store is to the last word of the line, memory corruption occurs.
5.1	October 2005	No changes.
5.0	May 2005	• Added optional tightly-coupled memory ports. Designers can add zero to four tightly-coupled instruction master ports, and zero to four tightly-coupled data master ports. • Made the data cache line size configurable. Designers can configure the data cache with the following line sizes: 4, 16, or 32 bytes. Previously, the data cache line size was fixed at 4 bytes. • Made instruction and data caches optional (previously, cache memories were always present). If the instruction cache is not present, the Nios II core does not have an instruction master port, and must use a tightly-coupled instruction memory. • Support for HardCopy devices (previous versions required a workaround to support HardCopy devices).

Version	Release Date	Notes
1.1	December 2004	• Added user-configurable options affecting multiply and shift operations. Now designers can choose one of three options: (1) Use embedded multiplier resources available in the target device family (previously available). (2) Use logic elements to implement multiply and shift hardware (new option). (3) Omit multiply hardware. Shift operations take one cycle per bit shifted; multiply operations are emulated in software (new option). • Added `cpuid` control register. • Bug Fix: Interrupts that were disabled by `wrctl ienable` remained enabled for one clock cycle following the `wrctl` instruction. Now the instruction following such a `wrctl` cannot be interrupted.
1.01	September 2004	• Bug Fixes: (1) When a store to memory is followed immediately in the pipeline by a load from the same memory location, and the memory location is held in the data cache, the load may return invalid data. This situation can occur in C code compiled with optimization off (-O0). (2) The SOPC Builder top-level system module included an extra, unnecessary output port for systems with very small address spaces.
1.0	May 2004	Initial release of the Nios II/f core.

Table 6-6: Nios II/f Core Revisions

Version	Release Date	Notes
14.0	January 2015	Initial release of the Nios IIf core.

Nios II/s Core

Table 6-7: Nios II/s Core Revisions

Version	Release Date	Notes
13.1	November 2013	• Added support for enhanced floating-point custom instructions
11.0	May 2011	No changes.
10.1	December 2010	No changes.
10.0	July 2010	No changes.

Version	Release Date	Notes
9.1	November 2009	No changes.
9.0	March 2009	No changes.
8.1	November 2008	No changes.
8.0	May 2008	Implemented the illegal instruction exception.
7.2	October 2007	Implemented the `jmpi` instruction.
7.1	May 2007	No changes.
7.0	March 2007	No changes.
6.1	November 2006	No changes.
6.0	May 2006	Cycle count for `flushi` and `initi` instructions changes from 1 to 4 cycles.
5.1	October 2005	No changes.
5.0	May 2005	• Added optional tightly-coupled memory ports. Designers can add zero to four tightly-coupled instruction master ports. • Made instruction cache optional (previously instruction cache was always present). If the instruction cache is not present, the Nios II core does not have an instruction master port, and must use a tightly-coupled instruction memory. • Support for HardCopy devices (previous versions required a workaround to support HardCopy devices).
1.1	December 2004	• Added user-configurable options affecting multiply and shift operations. Now designers can choose one of three options: (1) Use embedded multiplier resources available in the target device family (previously available). (2) Use logic elements to implement multiply and shift hardware (new option). (3) Omit multiply hardware. Shift operations take one cycle per bit shifted; multiply operations are emulated in software (new option). • Added user-configurable option to include divide hardware in the ALU. Previously this option was available for only the Nios II/f core. • Added `cpuid` control register.
1.01	September 2004	Bug fix: The SOPC Builder top-level system module included an extra, unnecessary output port for systems with very small address spaces.

Version	Release Date	Notes
1.0	May 2004	Initial release of the Nios II/s core.

14.0	January 2015	Initial release of the Nios II s core.

Nios II/e Core

Table 6-9: Nios II/e Core Revisions

Version	Release Date	Notes
13.1	November 2013	• Added support for enhanced floating-point custom instructions
11.0	May 2011	No changes.
10.1	December 2010	No changes.
10.0	July 2010	No changes.
9.1	November 2009	No changes.
9.0	March 2009	No changes.
8.1	November 2008	No changes.
8.0	May 2008	Implemented the illegal instruction exception.
7.2	October 2007	Implemented the `jmpi` instruction.
7.1	May 2007	No changes.
7.0	March 2007	No changes.
6.1	November 2006	No changes.
6.0	May 2006	No changes.
5.1	October 2005	No changes.
5.0	May 2005	Support for HardCopy devices (previous versions required a workaround to support HardCopy devices).
1.1	December 2004	Added `cpuid` control register.
1.01	September 2004	Bug fix: The SOPC Builder top-level system module included an extra, unnecessary output port for systems with very small address spaces.

Version	Release Date	Notes
1.0	May 2004	Initial release of the Nios II/e core.

Table 6-10: Nios II/e Core Revisions

Version	Release Date	Notes
14.0	January 2015	Initial release of the Nios II e core.

JTAG Debug Module Revisions

JTAG debug module revisions augment the debug capabilities of the processor, or fix bugs isolated within the JTAG debug module logic.

Table 6-11: JTAG Debug Module Revisions

Version	Release Date	Notes
11.0	May 2011	No changes.
10.1	December 2010	No changes.
10.0	July 2010	No changes.
9.1	November 2009	No changes.
9.0	March 2009	No changes.
8.1	November 2008	No changes.
8.0	May 2008	No changes.
7.2	October 2007	No changes.
7.1	May 2007	No changes.
7.0	March 2007	No changes.
6.1	November 2006	No changes.
6.0	May 2006	No changes.
5.1	October 2005	No changes.
5.0	May 2005	Support for HardCopy devices (previous versions of the JTAG debug module did not support HardCopy devices).
1.1	December 2004	Bug fix: When using the Nios II/s and Nios II/f cores, hardware breakpoints may have falsely triggered when placed on the instruction sequentially following a `jmp`, `trap`, or any branch instruction.

Version	Release Date	Notes
1.01	September 2004	• Feature enhancements: (1) Added the ability to trigger based on the instruction address. Uses include triggering trace control (trace on/off), sequential triggers, and trigger in/out signal generation. (2) Enhanced trace collection such that collection can be stopped when the trace buffer is full without halting the processor. (3) Armed triggers – Enhanced trigger logic to support two levels of triggers, or "armed triggers"; enabling the use of "Event A then event B" trigger definitions. • Bug fixes: (1) On the Nios II/s core, trace data sometimes recorded incorrect addresses during interrupt processing. (2) Under certain circumstances, captured trace data appeared to start earlier or later than the desired trigger location. (3) During debugging, the processor would hang if a hardware breakpoint and an interrupt occurred simultaneously.
1.0	May 2004	Initial release of the JTAG debug module.

Table 6-12: JTAG Debug Module Revisions

Version	Release Date	Notes
14.0	January 2015	Initial release of the JTAG debug module.

Processor Versions Revision History

Table 6-13: Document Revision History

Date	Version	Changes
April 2015	2015.04.02	Maintenance release.
February 2014	13.1.0	• Added information on ECC support. • Removed HardCopy information. • Removed references to SOPC Builder.
May 2011	11.0.0	Maintenance release.
December 2010	10.1.0	Maintenance release.
July 2010	10.0.0	Maintenance release.
November 2009	9.1.0	• Added external interrupt controller interface information. • Added shadow register set information.
March 2009	9.0.0	Maintenance release.

Date	Version	Changes
November 2008	8.1.0	Maintenance release.
May 2008	8.0.0	• Added MMU information. • Added MPU information. • Added advanced exception checking information. • Added `initda` instruction information.
October 2007	7.2.0	• Added `jmpi` instruction information. • Added exception handling information.
May 2007	7.1.0	• Updated tables to reflect no changes to cores. • Added table of contents to Introduction section. • Added Referenced Documents section.
March 2007	7.0.0	Updated tables to reflect no changes to cores.
November 2006	6.1.0	Updated tables to reflect no changes to cores.
May 2006	6.0.0	Updates for Nios II cores version 6.0.
October 2005	5.1.0	Updates for Nios II cores version 5.1.
May 2005	5.0.0	Updates for Nios II cores version 5.0.
September 2004	1.1	Updates for Nios II cores version 1.1.

Application Binary Interface 7

2016.10.28

NII51016

This chapter describes the Application Binary Interface (ABI) for the Nios® II processor. The ABI describes:

- How data is arranged in memory
- Behavior and structure of the stack
- Function calling conventions

Data Types

Table 7-1: Representation of Data C/C++ Types

Type	Size (Bytes)	Representation
char, signed char	1	two's complement (ASCII)
unsigned char	1	binary (ASCII)
short, signed short	2	two's complement
unsigned short	2	binary
int, signed int	4	two's complement
unsigned int	4	binary
long, signed long	4	two's complement
unsigned long	4	binary
float	4	IEEE
double	8	IEEE
pointer	4	binary
long long	8	two's complement
unsigned long long	8	binary

Memory Alignment

Contents in memory are aligned as follows:

- A function must be aligned to a minimum of 32-bit boundary.
- The minimum alignment of a data element is its natural size. A data element larger than 32 bits need only be aligned to a 32-bit boundary.
- Structures, unions, and strings must be aligned to a minimum of 32 bits.
- Bit fields inside structures are always 32-bit aligned.

Register Usage

The ABI adds additional usage conventions to the Nios II register file defined in the *Programming Model* chapter of the *Processor Reference Handbook*.

Table 7-2: Nios II ABI Register Usage

Register	Name	Used by Compiler	Callee Saved[41]	Normal Usage
r0	zero	v		0x00000000
r1	at			Assembler temporary
r2		v		Return value (least-significant 32 bits)
r3		v		Return value (most-significant 32 bits)
r4		v		Register arguments (first 32 bits)
r5		v		Register arguments (second 32 bits)
r6		v		Register arguments (third 32 bits)
r7		v		Register arguments (fourth 32 bits)
r8		v		Caller-saved general-purpose registers
r9		v		
r10		v		
r11		v		
r12		v		
r13		v		
r14		v		
r15		v		

[41] A function can use one of these registers if it saves it first. The function must restore the register's original value before exiting.

Register	Name	Used by Compiler	Callee Saved[41]	Normal Usage
r16		v	v	Callee-saved general-purpose registers
r17		v	v	
r18		v	v	
r19		v	v	
r20		v	v	
r21		v	v	
r22		v	[42]	
r23		v	[43]	
r24	et			Exception temporary
r25	bt			Break temporary
r26	gp	v		Global pointer
r27	sp	v		Stack pointer
r28	fp	v	[44]	Frame pointer
r29	ea			Exception return address
r30	ba			• Normal register set: Break return address • Shadow register sets: SSTATUS register
r31	ra	v		Return address

The endianness of values greater than 8 bits is little endian. The upper 8 bits of a value are stored at the higher byte address.

Related Information

- **Frame Pointer Elimination** on page 7-4
- **Programming Model** on page 3-1

Stacks

The stack grows downward (i.e. towards lower addresses). The stack pointer points to the last used slot. The frame pointer points to the saved frame pointer near the top of the stack frame.

[41] A function can use one of these registers if it saves it first. The function must restore the register's original value before exiting.

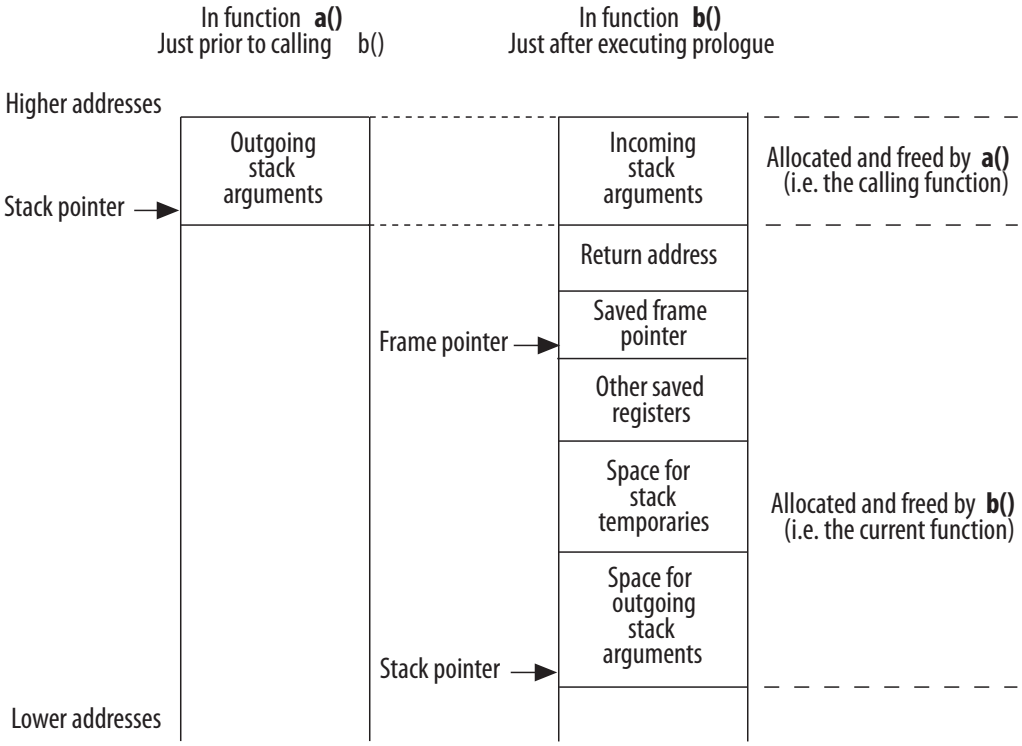
[42] In the GNU Linux operating system, r22 points to the global offset table (GOT). Otherwise, it is available as a callee-saved general-purpose register.

[43] In the GNU Linux operating system, r23 is used as the thread pointer. Otherwise, it is available as a callee-saved general-purpose register.

[44] If the frame pointer is not used, the register is available as a callee-saved temporary register. Refer to "Frame Pointer Elimination" .

The figure below shows an example of the structure of a current frame. In this case, function `a()` calls function `b()`, and the stack is shown before the call and after the prologue in the called function has completed.

Figure 7-1: Stack Pointer, Frame Pointer and the Current Frame



Each section of the current frame is aligned to a 32-bit boundary. The ABI requires the stack pointer be 32-bit aligned at all times.

Frame Pointer Elimination

The frame pointer is provided for debugger support. If you are not using a debugger, you can optimize your code by eliminating the frame pointer, using the `-fomit-frame-pointer` compiler option. When the frame pointer is eliminated, register `fp` is available as a temporary register.

Call Saved Registers

The compiler is responsible for generating code to save registers that need to be saved on entry to a function, and to restore the registers on exit. If there are any such registers, they are saved on the stack, from high to low addresses, in the following order: `ra`, `fp`, `sp`, `gp`, `r25`, `r24`, `r23`, `r22`, `r21`, `r20`, `r19`, `r18`, `r17`, `r16`, `r15`, `r14`, `r13`, `r12`, `r11`, `r10`, `r9`, `r8`, `r7`, `r6`, `r5`, `r4`, `r3`, and `r2`. Stack space is not allocated for registers that are not saved.

Further Examples of Stacks

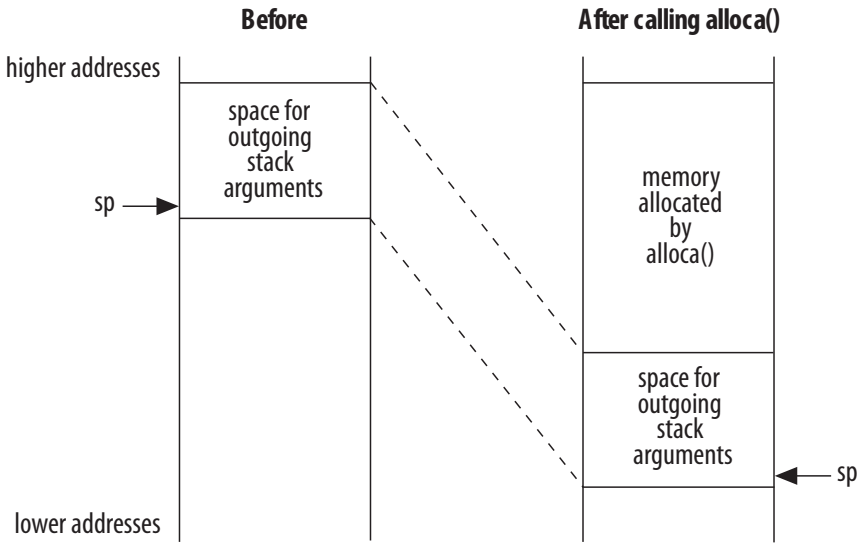
There are a number of special cases for stack layout, which are described in this section.

Stack Frame for a Function With alloca()

The Nios II stack frame implementation provides support for the `alloca()` function, defined in the Berkeley Software Distribution (BSD) extension to C, and implemented by the gcc compiler. The space allocated by `alloca()` replaces the outgoing arguments and the outgoing arguments get new space allocated at the bottom of the frame.

Note: The Nios II C/C++ compiler maintains a frame pointer for any function that calls `alloca()`, even if `-fomit-frame-pointer` is spec if ed

Figure 7-2: Stack Frame after Calling alloca()

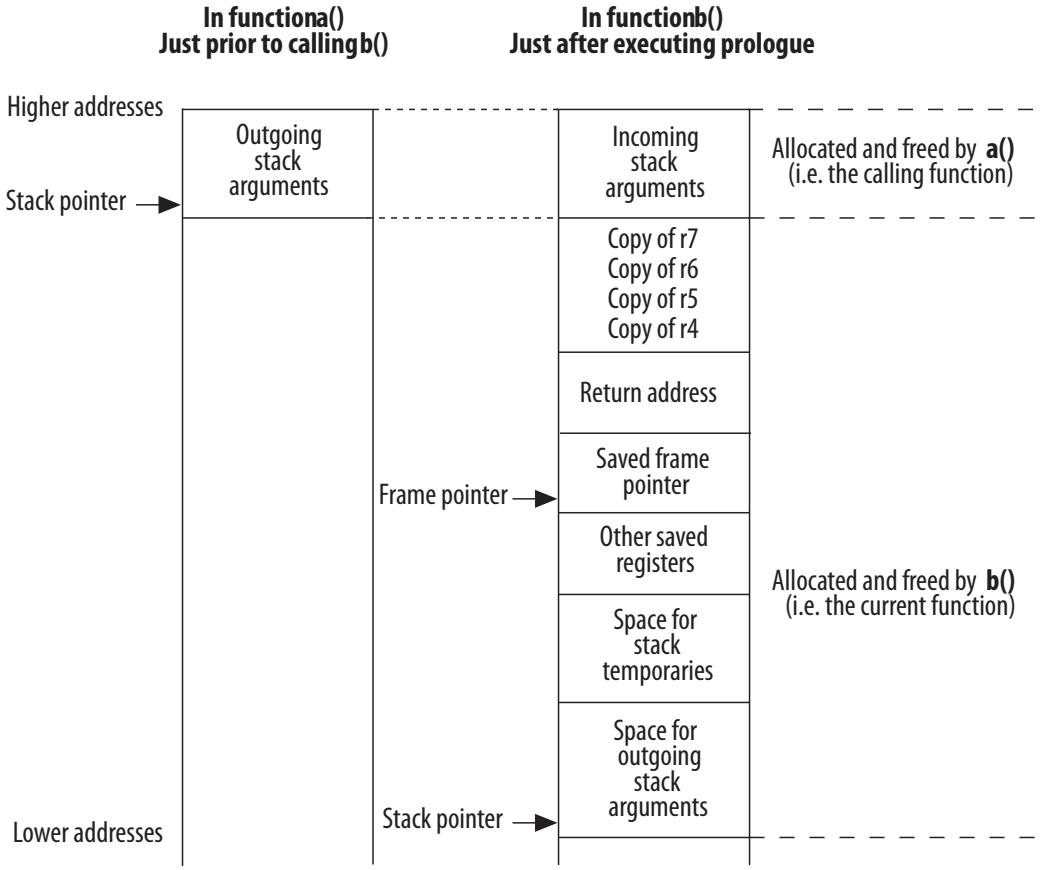


Stack Frame for a Function with Variable Arguments

Functions that take variable arguments (`varargs`) still have their first 16 bytes of arguments arriving in registers `r4` through `r7`, just like other functions.

In order for `varargs` to work, functions that take variable arguments allocate 16 extra bytes of storage on the stack. They copy to the stack the first 16 bytes of their arguments from registers `r4` through `r7` as shown below.

Figure 7-3: Stack Frame Using Variable Arguments



Stack Frame for a Function with Structures Passed By Value

Functions that take `struct` value arguments still have their first 16 bytes of arguments arriving in registers `r4` through `r7`, just like other functions.

If part of a structure is passed using registers, the function might need to copy the register contents back to the stack. This operation is similar to that required in the variable arguments case as shown in the figure above, *Stack Frame Using Variable Arguments*.

Related Information

Stack Frame for a Function with Variable Arguments on page 7-5

Function Prologues

The Nios II C/C++ compiler generates function prologues that allocate the stack frame of a function for storage of stack temporaries and outgoing arguments. In addition, each prologue is responsible for saving the state of the calling function. This entails saving certain registers on the stack. These registers, the callee-saved registers, are listed in Nios II ABI Register Usage Table in the Register Usage section. A function prologue is required to save a callee-saved register only if the function uses the register.

Given the function prologue algorithm, when doing a back trace, a debugger can disassemble instructions and reconstruct the processor state of the calling function.

Note: An even better way to find out what the prologue has done is to use information stored in the DWARF-2 debugging fields of the executable and linkable format (**.elf**) file.

The instructions found in a Nios II function prologue perform the following tasks:

- Adjust the stack pointer (to allocate the frame)
- Store registers to the frame
- Set the frame pointer to the location of the saved frame pointer

Example 7-1: A function prologue

```
/* Adjust the stack pointer */
addi    sp, sp, -16   /* make a 16-byte frame */

/* Store registers to the frame */
stw     ra, 12(sp)    /* store the return address */
stw     fp, 8(sp)     /* store the frame pointer*/
stw     r16, 4(sp)    /* store callee-saved register */
stw     r17, 0(sp)    /* store callee-saved register */

/* Set the new frame pointer */
addi    fp, sp, 8
```

Related Information

Register Usage on page 7-2

Prologue Variations

The following variations can occur in a prologue:

- If the function's frame size is greater than 32,767 bytes, extra temporary registers are used in the calculation of the new stack pointer as well as for the offsets of where to store callee-saved registers. The extra registers are needed because of the maximum size of immediate values allowed by the processor.
- If the frame pointer is not in use, the final instruction, recalculating the frame pointer, is not generated.
- If variable arguments are used, extra instructions store the argument registers on the stack.
- If the compiler designates the function as a leaf function, the return address is not saved.
- If optimizations are on, especially instruction scheduling, the order of the instructions might change and become interlaced with instructions located after the prologue.

Arguments and Return Values

This section discusses the details of passing arguments to functions and returning values from functions.

Arguments

The first 16 bytes to a function are passed in registers `r4` through `r7`. The arguments are passed as if a structure containing the types of the arguments were constructed, and the first 16 bytes of the structure are located in `r4` through `r7`.

A simple example:

```
int function (int a, int b);
```

The equivalent structure representing the arguments is:

```
struct { int a; int b; };
```

The first 16 bytes of the `struct` are assigned to `r4` through `r7`. Therefore `r4` is assigned the value of a and `r5` the value of b.

The first 16 bytes to a function taking variable arguments are passed the same way as a function not taking variable arguments. The called function must clean up the stack as necessary to support the variable arguments.

Refer to Stack Frame for a Function with Variable Arguments

Related Information

Stack Frame for a Function with Variable Arguments on page 7-5

Return Values

Return values of types up to 8 bytes are returned in `r2` and `r3`. For return values greater than 8 bytes, the caller must allocate memory for the result and must pass the address of the result memory as a hidden zero argument.

The hidden zero argument is best explained through an example.

Example 7-2: Returned struct

```
/* b() computes a structure-type result and returns it */
STRUCT b(int i, int j)
{
   ...
   return result;
}
void a(...)
{
   ...
   value = b(i, j);
}
```

In the example above, if the result type is no larger than 8 bytes, `b()` returns its result in `r2` and `r3`.

If the return type is larger than 8 bytes, the Nios II C/C++ compiler treats this program as if `a()` had passed a pointer to `b()`. The example below shows how the Nios II C/C++ compiler sees the code in the Returned Struct example above.

Example 7-3: Returned struct is Larger than 8 Bytes

```
void b(STRUCT *p_result, int i, int j)
{
   ...
   *p_result = result;
}

void a(...)
{
   STRUCT value;
   ...
```

```
    b(&value, i, j);
}
```

DWARF-2 Definition

Registers `r0` through `r31` are assigned numbers 0 through 31 in all DWARF-2 debugging sections.

Object Files

Table 7-3: Nios II-Specific ELF Header Values

Member	Value
`e_ident[EI_CLASS]`	`ELFCLASS32`
`e_ident[EI_DATA]`	`ELFDATA2LSB`
`e_machine`	`EM_ALTERA_NIOS2` == 113

Relocation

In a Nios II object file, each relocatable address reference possesses a relocation type. The relocation type specifies how to calculate the relocated address. The bit mask specifies where the address is found in the instruction.

Table 7-4: Nios II Relocation Calculation

Name	Value	Overflow check (45)	Relocated Address R	Bit Mask M	Bit Shift B
R_NIOS2_NONE	0	n/a	None	n/a	n/a
R_NIOS2_S16	1	Yes	S + A	0x003FFFC0	6
R_NIOS2_U16	2	Yes	S + A	0x003FFFC0	6
R_NIOS2_PCREL16	3	Yes	((S + A) – 4) – PC	0x003FFFC0	6
R_NIOS2_CALL26(46)	4	Yes	(S + A) >> 2	0xFFFFFFC0	6
R_NIOS2_CALL26_NOAT	41	No	(S + A) >> 2	0xFFFFFFC0	6
R_NIOS2_IMM5	5	Yes	(S + A) & 0x1F	0x000007C0	6
R_NIOS2_CACHE_OPX	6	Yes	(S + A) & 0x1F	0x07C00000	22

(45) For relocation types where no overflow check is performed, the relocated address is truncated to fit the instruction.

(46) Linker is permitted to clobber register AT in the course of resolving overflows

Name	Value	Overflow check (45)	Relocated Address R	Bit Mask M	Bit Shift B
R_NIOS2_IMM6	7	Yes	(S + A) & 0x3F	0x00000FC0	6
R_NIOS2_IMM8	8	Yes	(S + A) & 0xFF	0x00003FC0	6
R_NIOS2_HI16	9	No	((S + A) >> 16) & 0xFFFF	0x003FFFC0	6
R_NIOS2_LO16	10	No	(S + A) & 0xFFFF	0x003FFFC0	6
R_NIOS2_HIADJ16	11	No	Adj(S+A)	0x003FFFC0	6
R_NIOS2_BFD_RELOC_32	12	No	S + A	0xFFFFFFFF	0
R_NIOS2_BFD_RELOC_16	13	Yes	(S + A) & 0xFFFF	0x0000FFFF	0
R_NIOS2_BFD_RELOC_8	14	Yes	(S + A) & 0xFF	0x000000FF	0
R_NIOS2_GPREL	15	No	(S + A – GP) & 0xFFFF	0x003FFFC0	6
R_NIOS2_GNU_VTINHERIT	16	n/a	None	n/a	n/a
R_NIOS2_GNU_VTENTRY	17	n/a	None	n/a	n/a
R_NIOS2_UJMP	18	No	((S + A) >> 16) & 0xFFFF, (S + A + 4) & 0xFFFF	0x003FFFC0	6
R_NIOS2_CJMP	19	No	((S + A) >> 16) & 0xFFFF, (S + A + 4) & 0xFFFF	0x003FFFC0	6
R_NIOS2_CALLR	20	No	((S + A) >> 16) & 0xFFFF) (S + A + 4) & 0xFFFF	0x003FFFC0	6
R_NIOS2_ALIGN	21	n/a	None	n/a	n/a
R_NIOS2_GOT16	22(47)	Yes	G	0x003FFFC0	6
R_NIOS2_CALL16	23(47)	Yes	G	0x003FFFC0	6
R_NIOS2_GOTOFF_LO	24(47)	No	(S + A – GOT) & 0xFFFF	0x003FFFC0	6
R_NIOS2_GOTOFF_HA	25(47)	No	Adj (S + A – GOT)	0x003FFFC0	6

(45) For relocation types where no overflow check is performed, the relocated address is truncated to fit the instruction.

Name	Value	Overflow check (45)	Relocated Address R	Bit Mask M	Bit Shift B
R_NIOS2_PCREL_LO	26(47)	No	(S + A – PC) & 0xFFFF	0x003FFFC0	6
R_NIOS2_PCREL_HA	27(47)	No	Adj (S + A – PC)	0x003FFFC0	6
R_NIOS2_TLS_GD16	28(47)	Yes	Refer to Thread-Local Storage section	0x003FFFC0	6
R_NIOS2_TLS_LDM16	29(47)	Yes	Refer to Thread-Local Storage section	0x003FFFC0	6
R_NIOS2_TLS_LDO16	30(47)	Yes	Refer to Thread-Local Storage section	0x003FFFC0	6
R_NIOS2_TLS_IE16	31(47)	Yes	Refer to Thread-Local Storage section	0x003FFFC0	6
R_NIOS2_TLS_LE16	32(47)	Yes	Refer to Thread-Local Storage section	0x003FFFC0	6
R_NIOS2_TLS_DTPMOD	33(47)	No	Refer to Thread-Local Storage section	0xFFFFFFFF	0
R_NIOS2_TLS_DTPREL	34(47)	No	Refer to Thread-Local Storage section	0xFFFFFFFF	0
R_NIOS2_TLS_TPREL	35(47)	No	Refer to Thread-Local Storage section	0xFFFFFFFF	0
R_NIOS2_COPY	36(47)	No	Refer to Copy Relocation section.	n/a	n/a
R_NIOS2_GLOB_DAT	37(47)	No	S	0xFFFFFFFF	0
R_NIOS2_JUMP_SLOT	38(47)	No	Refer to Jump Slot Relocation section.	0xFFFFFFFF	0
R_NIOS2_RELATIVE	39(47)	No	BA+A	0xFFFFFFFF	0
R_NIOS2_GOTOFF	40(47)	No	S+A	0xFFFFFFFF	0
R_NIOS2_GOT_LO	42(47)	No	G & 0xFFFF	0x003FFFC0	6
R_NIOS2_GOT_HA	43(47)	No	Adj(G)	0x003FFFC0	6

(45) For relocation types where no overflow check is performed, the relocated address is truncated to fit the instruction.

Name	Value	Overflow check (45)	Relocated Address R	Bit Mask M	Bit Shift B
R_NIOS2_CALL_LO	44(47)	No	G & 0xFFFF	0x003FFFC0	6
R_NIOS2_CALL_HA	45(47)	No	Adj(G)	0x003FFFC0	6

Expressions in the table above use the following conventions:

- S: Symbol address
- A: Addend
- PC: Program counter
- GP: Global pointer
- Adj(X): (((X >> 16) & 0xFFFF) + ((X >> 15) & 0x1)) & 0xFFFF
- BA: The base address at which a shared library is loaded
- GOT: The value of the Global Offset Table (GOT) pointer (Linux only)
- G: The offset into the GOT for the GOT slot for symbol S (Linux only)

With the information in the table above, any Nios II instruction can be relocated by manipulating it as an unsigned 32-bit integer, as follows:

Xr = ((R << B) & M | (X & ~M));

where:

- R is the relocated address, calculated in the above table
- B is the bit shift
- M is the bit mask
- X is the original instruction
- Xr is the relocated instruction

ABI for Linux Systems

This section describes details specific to Linux systems beyond the Linux-specific information in Nios II ABI Register Usage Table and the Relocation Calculation Table.

Related Information

- **Relocation** on page 7-9

(45) For relocation types where no overflow check is performed, the relocated address is truncated to fit the instruction.
(47) Relocation support is provided for Linux systems.

- **Register Usage** on page 7-2

Linux Toolchain Relocation Information

Dynamic relocations can appear in the runtime relocation sections of executables and shared objects, but never appear in object files (with the exception of R_NIOS2_TLS_DTPREL, which is used for debug information). No other relocations are dynamic.

Table 7-5: Dynamic Relocations

R_NIOS2_TLS_DTPMOD
R_NIOS2_TLS_DTPREL
R_NIOS2_TLS_TPREL
R_NIOS2_COPY
R_NIOS2_GLOB_DAT
R_NIOS2_JUMP_SLOT
R_NIOS2_RELATIVE

A global offset table (GOT) entry referenced using R_NIOS2_GOT16, R_NIOS2_GOT_LO as well as R_NIOS2_GOT_HA must be resolved at load time. A GOT entry referenced only using R_NIOS2_CALL16, R_NIOS2_CALL_LO as well as R_NIOS2_CALL_HA can initially refer to a procedure linkage table (PLT) entry and then be resolved lazily.

Because the TP-relative relocations are 16-bit relocations, no dynamic object using local dynamic or local executable thread-local storage (TLS) can have more than 64 KB of TLS data. New relocations might be added to support this in the future.

Several new assembler operators are defined to generate the Linux-specific relocations, as listed in the table below.

Table 7-6: Relocation and Operator

Relocation	Operator
R_NIOS2_GOT16	`%got`
R_NIOS2_CALL16	`%call`
R_NIOS2_GOTOFF_LO	`%gotoff_hiadj`
R_NIOS2_GOTOFF_HA	`%gotoff_lo`
R_NIOS2_PCREL_LO	`%hiadj`
R_NIOS2_PCREL_HA	`%lo`
R_NIOS2_TLS_GD16	`%tls_gd`
R_NIOS2_TLS_LDM16	`%tls_ldm`
R_NIOS2_TLS_LDO16	`%tls_ldo`
R_NIOS2_TLS_IE16	`%tls_ie`
R_NIOS2_TLS_LE16	`%tls_le`

Relocation	Operator
R_NIOS2_TLS_DTPREL	%tls_ldo
R_NIOS2_GOTOFF	%gotoff
R_NIOS2_GOT_LO	%got_lo
R_NIOS2_GOT_HA	%got_hiadj
R_NIOS2_CALL_LO	%call_lo
R_NIOS2_CALL_HA	%call_hiadj

The %hiadj and %lo operators generate PC-relative or non-PC-relative relocations, depending whether the expression being relocated is PC-relative. For instance, %hiadj(_gp_got - .) generates R_NIOS2_PCREL_HA. %tls_ldo generates R_NIOS2_TLS_LDO16 when used as an immediate operand, and R_NIOS2_TLS_DTPREL when used with the .word directive.

Copy Relocation

The R_NIOS2_COPY relocation is used to mark variables allocated in the executable that are defined in a shared library. The variable's initial value is copied from the shared library to the relocated location.

Jump Slot Relocation

Jump slot relocations are used for the PLT.

For information about the PLT, refer to "Procedure Linkage Table" section.

Thread-Local Storage

The processor uses the Variant I model for thread-local storage.

The end of the thread control block (TCB) is located 0x7000 bytes before the thread pointer. The TCB is eight bytes long. The first word is the dynamic thread pointer (DTV) pointer and the second word is reserved. Each module's dynamic thread pointer is biased by 0x8000 (when retrieved using __tls_get_addr). The thread library can store additional private information before the TCB.

In the GNU Linux toolchain, the GOT pointer (_gp_got) is always kept in r22, and the thread pointer is always kept in r23.

In the following examples, any registers can be used, except that the argument to __tls_get_addr is always passed in r4 and its return value is always returned in r2. Calls to __tls_get_addr must use the normal position-independent code (PIC) calling convention in PIC code; these sequences are for example only, and the compiler might generate different sequences. No linker relaxations are defined.

Example 7-4: General Dynamic Model

```
addi r4, r22, %tls_gd(x)          # R_NIOS2_TLS_GD16 x
call __tls_get_addr               # R_NIOS2_CALL26 __tls_get_addr
# Address of x in r2
```

In the general dynamic model, a two-word GOT slot is allocated for x, as shown in "GOT Slot for General Dynamic Model" example.

Example 7-5: GOT Slot for General Dynamic Model

```
GOT[n]              R_NIOS2_TLS_DTPMOD x
GOT[n+1]            R_NIOS2_TLS_DTPREL x
```

Example 7-6: Local Dynamic Model

```
addi r4, r22, %tls_ldm(x)           # R_NIOS2_TLS_LDM16 x
call __tls_get_addr                 # R_NIOS2_CALL26 __tls_get_addr
addi r5, r2, %tls_ldo(x)            # R_NIOS2_TLS_LDO16 x
# Address of x in r5
ldw r6, %tls_ldo(x2)(r2)            # R_NIOS2_TLS_LDO16 x2
# Value of x2 in r6
```

One 2-word GOT slot is allocated for all R_NIOS2_TLS_LDM16 operations in the linked object. Any thread-local symbol in this object can be used, as shown in "GOT Slot with Thread-Local Storage" example.

Example 7-7: GOT Slot with Thread-Local Storage

```
GOT[n]          R_NIOS2_TLS_DTPMOD x
GOT[n+1]        0
```

Example 7-8: Initial Exec Model

```
ldw       r4, %tls_ie(x)(r22)       # R_NIOS2_TLS_IE16 x
add       r4, r23, r4
# Address of x in r4
```

A single GOT slot is allocated to hold the offset of x from the thread pointer, as shown in "GOT SLot for Initial Exec Model" example.

Example 7-9: GOT Slot for Initial Exec Model

```
GOT[n]          R_NIOS2_TLS_TPREL x
```

Example 7-10: Local Exec Model

```
addi       r4, r23, %tls_le(x)       # R_NIOS2_TLS_LE16 x
# Address of x in r4
```

There is no GOT slot associated with the local exec model.

Debug information uses the GNU extension DW_OP_GNU_push_tls_address.

Example 7-11: Debug Information

```
.byte 0x03                # DW_OP_addr
.word %tls_ldo(x)         # R_NIOS2_TLS_DTPREL x
.byte 0xe0                # DW_OP_GNU_push_tls_address
```

Linux Function Calls

Register `r23` is reserved for the thread pointer on GNU Linux systems. It is initialized by the C library and it may be used directly for TLS access, but not modified. On non-Linux systems `r23` is a general-purpose, callee-saved register.

The global pointer, `r26` or `gp`, is globally fixed. It is initialized in startup code and always valid on entry to a function. This method does not allow for multiple `gp` values, so `gp`-relative data references are only possible in the main application (that is, from position dependent code). `gp` is only used for small data access, not GOT access, because code compiled as PIC may be used from shared libraries. The linker may take advantage of `gp` for shorter PLT sequences when the addresses are in range. The compiler needs an option to disable use of `gprel`; the option is necessary for applications with excessive amounts of small data. For comparison, XUL (Mozilla display engine, 16 MB code, 2 MB data) has only 27 KB of small data and the limit is 64 KB. This option is separate from -G 0, because -G 0 creates ABI incompatibility. A file compiled with -G 0 puts global `int` variables into `.data` but files compiled with -G 8 expect such `int` variables to be in `.sdata`.

PIC code which needs a GOT pointer needs to initialize the pointer locally using `nextpc`; the GOT pointer is not passed during function calls. This approach is compatible with both static relocatable binaries and System V style shared objects. A separate ABI is needed for shared objects with independently relocatable text and data.

Stack alignment is 32-bit. The frame pointer points at the top of the stack when it is in use, to simplify backtracing. Insert `alloca` between the local variables and the outgoing arguments. The stack pointer points to the bottom of the outgoing argument area.

A large `struct` return value is handled by passing a pointer in the first argument register (not the disjoint return value register).

Linux Operating System Call Interface

Table 7-7: Signals for Unhandled Instruction-Related Exceptions

Exception	Signal
Supervisor-only instruction address	`SIGSEGV`

Exception	Signal
TLB permission violation (execute)	SIGSEGV
Supervisor-only instruction	SIGILL
Unimplemented instruction	SIGILL
Illegal instruction	SIGILL
Break instruction	SIGTRAP
Supervisor-only data address	SIGSEGV
Misaligned data address	SIGBUS
Misaligned destination address	SIGBUS
Division error	SIGFPE
TLB Permission Violation (read)	SIGSEGV
TLB Permission Violation (write)	SIGSEGV

There are no floating-point exceptions. The optional floating point unit (FPU) does not support exceptions and any process wanting exact IEEE conformance needs to use a soft-float library (possibly accelerated by use of the attached FPU).

The `break` instruction in a user process might generate a `SIGTRAP` signal for that process, but is not required to. Userspace programs should not use the `break` instruction and userspace debuggers should not insert one. If no hardware debugger is connected, the OS should assure that the `break` instruction does not cause the system to stop responding.

For information about userspace debugging, refer to "Userspace Breakpoints".

The page size is 4 KB. Virtual addresses in user mode are all below 2 GB due to the MMU design. The NULL page is not mapped.

Related Information

Userspace Breakpoints on page 7-23

Linux Process Initialization

The stack pointer, sp, points to the argument count on the stack.

Table 7-8: Stack Initial State at User Process Start

Purpose	Start Address	Length
Unspecified	High addresses	
Referenced strings		Varies
Unspecified		
Null auxilliary vector entry		4 bytes
Auxilliary vector entries		8 bytes each
NULL terminator for envp		4 bytes

Purpose	Start Address	Length
Environment pointers	sp + 8 + 4 × argc	4 bytes each
NULL terminator for argv	sp + 4 + 4 × argc	4 bytes
Argument pointers	sp + 4	4 bytes each
Argument count	sp	4 bytes
Unspecified	Low addresses	

If the application should register a destructor function with `atexit`, the pointer is placed in `r4`. Otherwise `r4` is zero.

The contents of all other registers are unspecified. User code should set `fp` to zero to mark the end of the frame chain.

The auxiliary vector is a series of pairs of 32-bit tag and 32-bit value, terminated by an `AT_NULL` tag.

Linux Position-Independent Code

Every position-independent code (PIC) function which uses global data or global functions must load the value of the GOT pointer into a register. Any available register may be used. If a caller-saved register is used the function must save and restore it around calls. If a callee-saved register is used it must be saved and restored around the current function. Examples in this document use `r22` for the GOT pointer.

The GOT pointer is loaded using a PC-relative offset to the `_gp_got` symbol, as shown below.

Example 7-12: Loading the GOT Pointer

```
nextpc r22
1:
   orhi r1, %hiadj(_gp_got - 1b) # R_NIOS2_PCREL_HA _gp_got
   addi r1, r1, %lo(_gp_got - 1b) # R_NIOS2_PCREL_LO _gp_got - 4
   add r22, r22, r1
   # GOT pointer in r22
```

Data may be accessed by loading its location from the GOT. A single word GOT entry is generated for each referenced symbol.

Example 7-13: Small GOT Model Entry for Global Symbols

```
addi   r3, r22, %got(x)      # R_NIOS2_GOT16

GOT[n]                         R_NIOS2_GLOB_DAT x
```

Example 7-14: Large GOT Model Entry for Global Symbols

```
movhi r3,     %got_hiadj(x)    # R_NIOS2_GOT_HA
addi  r3, r3, %got_lo(x)       # R_NIOS2_GOT_LO
add   r3, r3, r22
```

```
GOT[n]                          R_NIOS2_GLOB_DAT x
```

For local symbols, the symbolic reference to *x* is replaced by a relative relocation against symbol zero, with the link time address of *x* as an addend, as shown in the example below.

Example 7-15: Local Symbols for small GOT Model

```
addi   r3, r22, %got(x)         # R_NIOS2_GOT16

GOT[n]                            R_NIOS2_RELATIVE +x
```

Example 7-16: Local Symbols for large GOT Model

```
movhi r3,     %got_hiadj(x)     # R_NIOS2_GOT_HA
addi  r3, r3, %got_lo(x)        # R_NIOS2_GOT_LO
add   r3, r3, r22

GOT[n]                            R_NIOS2_RELATIVE +x
```

The `call` and `jmpi` instructions are not available in position-independent code. Instead, all calls are made through the GOT. Function addresses may be loaded with `%call`, which allows lazy binding. To initialize a function pointer, load the address of the function with `%got` instead. If no input object requires the address of the function its GOT entry is placed in the PLT GOT for lazy binding, as shown in the example below.

For information about the PLT, refer to the "Procedure Linkage Table" section.

Example 7-17: Small GOT Model entry in PLT GOT

```
ldw      r3, %call(fun)(r22)      # R_NIOS2_CALL16 fun
callr    r3

PLTGOT[n]                           R_NIOS_JUMP_SLOT fun
```

Example 7-18: Large GOT Model entry in PLT GOT

```
movhi r3,     %call_hiadj(x)     # R_NIOS2_CALL_HA
addi  r3, r3, %call_lo(x)        # R_NIOS2_CALL_LO
add   r3, r3, r22
ldw   r3, 0(r3)
callr r3

PLTGOT[n]                           R_NIOS_JUMP_SLOT fun
```

When a function or variable resides in the current shared object at compile time, it can be accessed via a PC-relative or GOT-relative offset, as shown below.

Example 7-19: Accessing Function or Variable in Current Shared Object

```
orhi      r3, %gotoff_hiadj(x)       # R_NIOS2_GOTOFF_HA x
addi      r3, r3, %gotoff_lo(x)      # R_NIOS2_GOTOFF_LO x
add       r3, r22, r3
# Address of x in r3
```

Multiway branches such as switch statements can be implemented with a table of GOT-relative offsets, as shown below.

Example 7-20: Switch Statement Implemented with Table

```
# Scaled table offset in r4
   orhi      r3, %gotoff_hiadj(Ltable)       # R_NIOS2_GOTOFF_HA Ltable
   addi      r3, r3, %gotoff_lo(Ltable)      # R_NIOS2_GOTOFF_LO Ltable
   add       r3, r22, r3                     # r3 == &Ltable
   add       r3, r3, r4
   ldw       r4, 0(r3)                       # r3 == Ltable[index]
   add       r4, r4, r22                     # Convert offset into destina-
tion
   jmp       r4
   ...
Ltable:
   .word %gotoff(Label1)
   .word %gotoff(Label2)
   .word %gotoff(Label3)
```

Related Information

Procedure Linkage Table on page 7-21

Linux Program Loading and Dynamic Linking

Global Offset Table

Because shared libraries are position-independent, they can not contain absolute addresses for symbols. Instead, addresses are loaded from the GOT.

The first word of the GOT is filled in by the link editor with the unrelocated address of the `_DYNAMIC`, which is at the start of the dynamic section. The second and third words are reserved for the dynamic linker.

For information about the dynamic linker, refer to the "Procedure Linkage Table" section.

The linker-defined symbol `_GLOBAL_OFFSET_TABLE_` points to the reserved entries at the beginning of the GOT. The linker-defined symbol `_gp_got` points to the base address used for GOT-relative relocations. The value of `_gp_got` might vary between object files if the linker creates multiple GOT sections.

Related Information

Procedure Linkage Table on page 7-21

Function Addresses

Function addresses use the same `SHN_UNDEF` and `st_value` convention for PLT entries as in other architectures, such as x86_64.

Procedure Linkage Table

Function calls in a position-dependent executable may use the `call` and `jmpi` instructions, which address the contents of a 256-MB segment. They may also use the `%lo`, `%hi`, and `%hiadj` operators to take the address of a function. If the function is in another shared object, the link editor creates a callable stub in the executable called a PLT entry. The PLT entry loads the address of the called function from the PLT GOT (a region at the start of the GOT) and transfers control to it.

The PLT GOT entry needs a relocation referring to the final symbol, of type R_NIOS2_JUMP_SLOT. The dynamic linker may immediately resolve it, or may leave it unmodified for lazy binding. The link editor fills in an initial value pointing to the lazy binding stubs at the start of the PLT section.

Each PLT entry appears as shown in the example below.

Example 7-21: PLT Entry

```
.PLTn:
   orhi   r15, r0, %hiadj(plt_got_slot_address)
   ldw    r15, %lo(plt_got_slot_address)(r15)
   jmp    r15
```

The example below shows the PLT entry when the PLT GOT is close enough to the small data area for a relative jump.

Example 7-22: PLT Entry Near Small Data Area

```
.PLTn:
   ldw    r15, %gprel(plt_got_slot_address)(gp)
   jmp    r15
```

Example 7-23: Initial PLT Entry

```
res_0:
   br .PLTresolve
   ...
.PLTresolve:
   orhi    r14, r0, %hiadj(res_0)
   addi    r14, r14, %lo(res_0)
   sub     r15, r15, r14
   orhi    r13, %hiadj(_GLOBAL_OFFSET_TABLE_)
   ldw     r14, %lo(_GLOBAL_OFFSET_TABLE_+4)(r13)
   ldw     r13, %lo(_GLOBAL_OFFSET_TABLE_+8)(r13)
   jmp     r13
```

In front of the initial PLT entry, a series of branches start of the initial entry (the `nextpc` instruction). There is one branch for each PLT entry, labelled `res_0` through `res_N`. The last several branches may be

replaced by nop instructions to improve performance. The link editor arranges for the Nth PLT entry to point to the Nth branch; `res_N – res_0` is four times the index into the `.rela.plt` section for the corresponding R_JUMP_SLOT relocation.

The dynamic linker initializes GOT[1] to a unique identifier for each library and GOT[2] to the address of the runtime resolver routine. In order for the two loads in `.PLTresolve` to share the same `%hiadj`, `_GLOBAL_OFFSET_TABLE_` must be aligned to a 16-byte boundary.

The runtime resolver receives the original function arguments in `r4` through `r7`, the shared library identifier from GOT[1] in `r14`, and the relocation index times four in `r15`. The resolver updates the corresponding PLT GOT entry so that the PLT entry transfers control directly to the target in the future, and then transfers control to the target.

In shared objects, the `call` and `jmpi` instructions can not be used because the library load address is not known at link time. Calls to functions outside the current shared object must pass through the GOT. The program loads function addresses using `%call`, and the link editor may arrange for such entries to be lazily bound. Because PLT entries are only used for lazy binding, shared object PLTs are smaller, as shown below.

Example 7-24: Shared Object PLT

```
.PLTn:
   orhi    r15, r0, %hiadj(index * 4)
   addi    r15, r15, %lo(index * 4)
   br      .PLTresolve
```

Example 7-25: Initial PLT Entry

```
.PLTresolve:
   nextpc    r14
   orhi      r13, r0, %hiadj(_GLOBAL_OFFSET_TABLE_)
   add       r13, r13, r14
   ldw       r14, %lo(_GLOBAL_OFFSET_TABLE_+4)(r13)
   ldw       r13, %lo(_GLOBAL_OFFSET_TABLE_+8)(r13)
   jmp       r13
```

If the initial PLT entry is out of range, the resolver can be inline, because it is only one instruction longer than a long branch, as shown below.

Example 7-26: Initial PLT Entry Out of Range

```
.PLTn:
   orhi      r15, r0, %hiadj(index * 4)
   addi      r15, r15, %lo(index * 4)
   nextpc    r14
   orhi      r13, r0, %hiadj(_GLOBAL_OFFSET_TABLE_)
   add       r13, r13, r14
   ldw       r14, %lo(_GLOBAL_OFFSET_TABLE_+4)(r13)
   ldw       r13, %lo(_GLOBAL_OFFSET_TABLE_+8)(r13)
   jmp       r13
```

Linux Program Interpreter

The program interpreter is **/lib/ld.so.1**.

Linux Initialization and Termination Functions

The implementation is responsible for calling `DT_INIT()`, `DT_INIT_ARRAY()`, `DT_PREINIT_ARRAY()`, `DT_FINI()`, and `DT_FINI_ARRAY()`.

Linux Conventions

System Calls

The Linux system call interface relies on the `trap` instruction with immediate argument zero. The system call number is passed in register `r2`. The arguments are passed in `r4`, `r5`, `r6`, `r7`, `r8`, and `r9` as necessary. The return value is written in `r2` on success, or a positive error number is written to `r2` on failure. A flag indicating successful completion, to distinguish error values from valid results, is written to `r7`; 0 indicates `syscall` success and 1 indicates `r2` contains a positive `errno` value.

Userspace Breakpoints

Userspace breakpoints are accomplished using the `trap` instruction with immediate operand 31 (all ones). The OS must distinguish this instruction from a `trap 0` system call and generate a `trap` signal.

Atomic Operations

The Nios II architecture does not have atomic operations (such as load linked and store conditional). Atomic operations are emulated using a kernel system call via the `trap` instruction. The toolchain provides intrinsic functions which perform the system call. Applications must use those functions rather than the system call directly. Atomic operations may be added in a future processor extension.

Processor Requirements

Linux requires that a hardware multiplier be present. The full 64-bit multiplier (`mulx` instructions) is not required.

Development Environment

The following object macros are defined:

- `NIOS2`
- `__NIOS2`
- `__NIOS2__`
- `nios2`
- `__nios2`
- `__nios2__`
- `nios2_little_endian`
- `__nios2_little_endian`
- `__nios2_little_endian__`

The object macro `__nios2_arch__` is predefined to 1 when you compile a program for Nios II R1 ISA and is predefined to 2 when you compile for Nios II R2 ISA.

Application Binary Interface Revision History

Table 7-9: Document Revision History

Date	Version	Changes
April 2015	2015.04.02	Updated Tables: • Relocation Calculation • Relocation and Operator New examples in *Linux Position-Independent Code* section: • Large GOT Entry for Global Symbols • Local Symbols for large GOT Model • Large GOT Model entry in PLT GOT *Linux Toolchain Relocation Information* section updated.
February 2014	13.1.0	Removed references to SOPC Builder.
May 2011	11.0.0	Maintenance release.
December 2010	10.1.0	Added Linux ABI section.
July 2010	10.0.0	• DWARF-2 register assignments • ELF header values • `r23` used as thread pointer for Linux • Linux toolchain relocation information • Symbol definitions for development environment
November 2009	9.1.0	Maintenance release.
March 2009	9.0.0	Backwards-compatible change to the `eret` instruction B field encoding.
November 2008	8.1.0	Maintenance release.
May 2008	8.0.0	• Frame pointer description updated. • Relocation table added.
October 2007	7.2.0	Maintenance release.
May 2007	7.1.0	• Added table of contents to Introduction section. • Added Referenced Documents section.
March 2007	7.0.0	Maintenance release.
November 2006	6.1.0	Maintenance release.
May 2006	6.0.0	Maintenance release.
October 2005	5.1.0	Maintenance release.
May 2005	5.0.0	Maintenance release.

Date	Version	Changes
September 2004	1.1	Maintenance release.
May 2004	1.0	Initial release.

Document Version	Changes
2019.04.30	Maintenance release
2018.04.18	• Implemented editorial enhancements. • Updated the information about object macros in *Development Environment*.
2016.10.28	Maintenance release.
2015.04.02	Initial release

Instruction Set Reference 8

2016.10.28

NII51017

This section introduces the instruction word format and provides a detailed reference of the Nios II instruction set.

Word Formats

There are three types of Nios II instruction word format: I-type, R-type, and J-type.

I-Type

The defining characteristic of the I-type instruction word format is that it contains an immediate value embedded within the instruction word. I-type instructions words contain:

- A 6-bit opcode field OP
- Two 5-bit register fields A and B
- A 16-bit immediate data field IMM16

In most cases, fields A and IMM16 specify the source operands, and field B specifies the destination register. IMM16 is considered signed except for logical operations and unsigned comparisons.

I-type instructions include arithmetic and logical operations such as `addi` and `andi`; branch operations; load and store operations; and cache management operations.

Table 8-1: I-Type Instruction Format

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										OP					

R-Type

The defining characteristic of the R-type instruction word format is that all arguments and results are specified as registers. R-type instructions contain:

- A 6-bit opcode field OP
- Three 5-bit register fields A, B, and C
- An 11-bit opcode-extension field OPX

In most cases, fields A and B specify the source operands, and field C specifies the destination register.

Some R-Type instructions embed a small immediate value in the five low-order bits of OPX. Unused bits in OPX are always 0.

R-type instructions include arithmetic and logical operations such as `add` and `nor`; comparison operations such as `cmpeq` and `cmplt`; the `custom` instruction; and other operations that need only register operands.

Table 8-2: R-Type Instruction Format

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					OPX
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OPX										OP					

J-Type

J-type instructions contain:

- A 6-bit opcode field
- A 26-bit immediate data field

J-type instructions, such as `call` and `jmpi`, transfer execution anywhere within a 256-MB range.

Table 8-3: J-Type Instruction Format

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IMM26															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM26										OP					

Instruction Opcodes

The OP field in the Nios II instruction word specifies the major class of an opcode as listed in the two tables below. Most values of OP are encodings for I-type instructions. One encoding, OP = 0x00, is the J-type instruction `call`. Another encoding, OP = 0x3a, is used for all R-type instructions, in which case, the OPX field differentiates the instructions. All undefined encodings of OP and OPX are reserved.

Table 8-4: OP Encodings

OP	Instruction	OP	Instruction	OP	Instruction	OP	Instruction
0x00	call	0x10	cmplti	0x20	cmpeqi	0x30	cmpltui

Assembler Pseudo-Instructions

Pseudo-instructions are used in assembly source code like regular assembly instructions. Each pseudo-instruction is implemented at the machine level using an equivalent instruction. The `movia` pseudo-instruction is the only exception, being implemented with two instructions. Most pseudo-instructions do not appear in disassembly views of machine code.

Table 8-6: Assembler Pseudo-Instructions

Pseudo-Instruction	Equivalent Instruction
`bgt rA, rB, label`	`blt rB, rA, label`
`bgtu rA, rB, label`	`bltu rB, rA, label`
`ble rA, rB, label`	`bge rB, rA, label`
`bleu rA, rB, label`	`bgeu rB, rA, label`
`cmpgt rC, rA, rB`	`cmplt rC, rB, rA`
`cmpgti rB, rA, IMMED`	`cmpgei rB, rA, (IMMED+1)`
`cmpgtu rC, rA, rB`	`cmpltu rC, rB, rA`
`cmpgtui rB, rA, IMMED`	`cmpgeui rB, rA, (IMMED+1)`
`cmple rC, rA, rB`	`cmpge rC, rB, rA`
`cmplei rB, rA, IMMED`	`cmplti rB, rA, (IMMED+1)`
`cmpleu rC, rA, rB`	`cmpgeu rC, rB, rA`
`cmpleui rB, rA, IMMED`	`cmpltui rB, rA, (IMMED+1)`
`mov rC, rA`	`add rC, rA, r0`
`movhi rB, IMMED`	`orhi rB, r0, IMMED`
`movi rB, IMMED`	`addi, rB, r0, IMMED`
`movia rB, label`	`orhi rB, r0, %hiadj(label)` `addi, rB, r0, %lo(label)`
`movui rB, IMMED`	`ori rB, r0, IMMED`
`nop`	`add r0, r0, r0`
`subi rB, rA, IMMED`	`addi rB, rA, (-IMMED)`

Refer to the *Application Binary Interface* chapter of the *Processor Reference Handbook* for more information about global pointers.

Related Information

Application Binary Interface on page 7-1

Assembler Macros

The Nios II assembler provides macros to extract halfwords from labels and from 32-bit immediate values. These macros return 16-bit signed values or 16-bit unsigned values depending on where they are used. When used with an instruction that requires a 16-bit signed immediate value, these macros return a value ranging from –32768 to 32767. When used with an instruction that requires a 16-bit unsigned immediate value, these macros return a value ranging from 0 to 65535.

Table 8-7: Assembler Macros

Macro	Description	Operation
`%lo(immed32)`	Extract bits [15..0] of immed32	immed32 & 0xFFFF
`%hi(immed32)`	Extract bits [31..16] of immed32	(immed32 >> 16) & 0xFFFF
`%hiadj(immed32)`	Extract bits [31..16] and adds bit 15 of immed32	((immed32 >> 16) & 0xFFFF) + ((immed32 >> 15) & 0x1)
`%gprel(immed32)`	Replace the immed32 address with an offset from the global pointer	immed32 –_gp

Refer to the *Application Binary Interface* chapter of the *Processor Reference Handbook* for more information about global pointers.

Related Information

Application Binary Interface on page 7-1

Instruction Set Reference

The following pages list all Nios II instruction mnemonics in alphabetical order.

Table 8-8: Notation Conventions

Notation	Meaning
X ← Y	X is written with Y
PC ← X	The program counter (PC) is written with address X; the instruction at X is the next instruction to execute
PC	The address of the assembly instruction in question
rA, rB, rC	One of the 32-bit general-purpose registers
prs.rA	General-purpose register rA in the previous register set
IMMn	An n-bit immediate value, embedded in the instruction word
IMMED	An immediate value

Notation	Meaning
X_n	The nth bit of X, where n = 0 is the LSB
$X_{n..m}$	Consecutive bits n through m of X
0xNNMM	Hexadecimal notation
X : Y	Bitwise concatenation For example, (0x12 : 0x34) = 0x1234
σ(X)	The value of X after being sign-extended to a full register-sized signed integer
X >> n	The value X after being right-shifted n bit positions
X << n	The value X after being left-shifted n bit positions
X & Y	Bitwise logical AND
X | Y	Bitwise logical OR
X ^ Y	Bitwise logical XOR
~X	Bitwise logical NOT (one's complement)
Mem8[X]	The byte located in data memory at byte address X
Mem16[X]	The halfword located in data memory at byte address X
Mem32[X]	The word located in data memory at byte address X
label	An address label specified in the assembly file
(signed) rX	The value of rX treated as a signed number
(unsigned) rX	The value of rX treated as an unsigned number

Note: All register operations apply to the current register set, except as noted.

The following exceptions are not listed for each instruction because they can occur on any instruction fetch:

- Supervisor-only instruction address
- Fast TLB miss (instruction)
- Double TLB miss (instruction)
- TLB permission violation (execute)
- MPU region violation (instruction)

For information about these and all Nios II exceptions, refer to the *Programming Model* chapter of the *Processor Reference Handbook*.

Related Information

Programming Model on page 3-1

add

Instruction	add

Operation	rC ← rA + rB
Assembler Syntax	`add rC, rA, rB`
Example	`add r6, r7, r8`
Description	Calculates the sum of rA and rB. Stores the result in rC. Used for both signed and unsigned addition.

Usage	Carry Detection (unsigned operands):
	Following an `add` operation, a carry out of the MSB can be detected by checking whether the unsigned sum is less than one of the unsigned operands. The carry bit can be written to a register, or a conditional branch can be taken based on the carry condition. The following code shows both cases:
	`add rC, rA, rB`
	`cmpltu rD, rC, rA`
	`add rC, rA, rB`
	`bltu rC, rA, label`
	`# The original add operation`
	`# rD is written with the carry bit`
	`# The original add operation`
	`# Branch if carry generated`
	Overflow Detection (signed operands):
	An overflow is detected when two positives are added and the sum is negative, or when two negatives are added and the sum is positive. The overflow condition can control a conditional branch, as shown in the following code:
	`add rC, rA, rB`
	`xor rD, rC, rA`
	`xor rE, rC, rB`
	`and rD, rD, rE`
	`blt rD, r0,label`
	`# The original add operation`
	`# Compare signs of sum and rA`
	`# Compare signs of sum and rB`
	`# Combine comparisons`
	`# Branch if overflow occurred`

Exceptions	None

Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x31
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x31					0					0x3A					

addi

Instruction	addi
Operation	rB ← rA + σ(IMM16)
Assembler Syntax	`addi rB, rA, IMM16`
Example	`addi r6, r7, -100`
Description	Sign-extends the 16-bit immediate value and adds it to the value of rA. Stores the sum in rB.

Usage	Carry Detection (unsigned operands):
	Following an `addi` operation, a carry out of the MSB can be detected by checking whether the unsigned sum is less than one of the unsigned operands. The carry bit can be written to a register, or a conditional branch can be taken based on the carry condition. The following code shows both cases:
	`addi rB, rA, IMM16`
	`cmpltu rD, rB, rA`
	`addi rB, rA, IMM16`
	`bltu rB, rA, label`
	`# The original add operation`
	`# rD is written with the carry bit`
	`# The original add operation`
	`# Branch if carry generated`
	Overflow Detection (signed operands):
	An overflow is detected when two positives are added and the sum is negative, or when two negatives are added and the sum is positive. The overflow condition can control a conditional branch, as shown in the following code:
	`addi rB, rA, IMM16`
	`xor rC, rB, rA`
	`xorhi rD, rB, IMM16`
	`and rC, rC, rD`
	`blt rC, r0,label`
	`# The original add operation`
	`# Compare signs of sum and rA`
	`# Compare signs of sum and IMM16`
	`# Combine comparisons`
	`# Branch if overflow occurred`

Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x04					

and

Instruction	bitwise logical and
Operation	rC ← rA & rB
Assembler Syntax	`and rC, rA, rB`
Example	`and r6, r7, r8`
Description	Calculates the bitwise logical AND of rA and rB and stores the result in rC.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x0e
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0e					0					0x3A					

andhi

Instruction	bitwise logical and immediate into high halfword
Operation	rB ← rA & (IMM16 : 0x0000)
Assembler Syntax	`andhi rB, rA, IMM16`

Example	`andhi r6, r7, 100`
Description	Calculates the bitwise logical AND of rA and (IMM16 : 0x0000) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x2c					

andi

Instruction	bitwise logical and immediate
Operation	rB ← rA & (0x0000 : IMM16)
Assembler Syntax	`andi rB, rA, IMM16`
Example	`andi r6, r7, 100`
Description	Calculates the bitwise logical AND of rA and (0x0000 : IMM16) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Fields															
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x0c					

beq

Instruction	branch if equal
Operation	if (rA == rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`beq rA, rB, label`
Example	`beq r6, r7, label`
Description	If rA == rB, then `beq` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `beq`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x26					

bge

Instruction	branch if greater than or equal signed
Operation	if ((signed) rA >= (signed) rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`bge rA, rB, label`
Example	`bge r6, r7, top_of_loop`
Description	If (signed) rA >= (signed) rB, then `bge` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `bge`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x0e					

bgeu

Instruction	branch if greater than or equal unsigned
Operation	if ((unsigned) rA >= (unsigned) rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`bgeu rA, rB, label`
Example	`bgeu r6, r7, top_of_loop`

Description	If (unsigned) rA >= (unsigned) rB, then bgeu transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following bgeu. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x2e					

bgt

Instruction	branch if greater than signed
Operation	if ((signed) rA > (signed) rB) then PC ← label else PC ← PC + 4
Assembler Syntax	`bgt rA, rB, label`
Example	`bgt r6, r7, top_of_loop`
Description	If (signed) rA > (signed) rB, then `bgt` transfers program control to the instruction at label.
Pseudo-instruction	`bgt` is implemented with the `blt` instruction by swapping the register operands.

bgtu

Instruction	branch if greater than unsigned

Operation	if ((unsigned) rA > (unsigned) rB) then PC ← label else PC ← PC + 4
Assembler Syntax	`bgtu rA, rB, label`
Example	`bgtu r6, r7, top_of_loop`
Description	If (unsigned) rA > (unsigned) rB, then `bgtu` transfers program control to the instruction at label.
Pseudo-instruction	`bgtu` is implemented with the `bltu` instruction by swapping the register operands.

ble

Instruction	branch if less than or equal signed
Operation	if ((signed) rA <= (signed) rB) then PC ← label else PC ← PC + 4
Assembler Syntax	`ble rA, rB, label`
Example	`ble r6, r7, top_of_loop`
Description	If (signed) rA <= (signed) rB, then `ble` transfers program control to the instruction at label.
Pseudo-instruction	`ble` is implemented with the `bge` instruction by swapping the register operands.

bleu

Instruction	branch if less than or equal to unsigned
Operation	if ((unsigned) rA <= (unsigned) rB) then PC ← label else PC ← PC + 4
Assembler Syntax	`bleu rA, rB, label`
Example	`bleu r6, r7, top_of_loop`

Description	If (unsigned) rA <= (unsigned) rB, then `bleu` transfers program counter to the instruction at label.
Pseudo-instruction	`bleu` is implemented with the `bgeu` instruction by swapping the register operands.

blt

Instruction	branch if less than signed
Operation	if ((signed) rA < (signed) rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`blt rA, rB, label`
Example	`blt r6, r7, top_of_loop`
Description	If (signed) rA < (signed) rB, then `blt` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `blt`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x16					

bltu

Instruction	branch if less than unsigned

Operation	if ((unsigned) rA < (unsigned) rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`bltu rA, rB, label`
Example	`bltu r6, r7, top_of_loop`
Description	If (unsigned) rA < (unsigned) rB, then `bltu` transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following `bltu`. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x36					

bne

Instruction	branch if not equal
Operation	if (rA != rB) then PC ← PC + 4 + σ(IMM16) else PC ← PC + 4
Assembler Syntax	`bne rA, rB, label`
Example	`bne r6, r7, top_of_loop`

Description	If rA != rB, then bne transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following bne. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x1e					

br

Instruction	unconditional branch
Operation	PC ← PC + 4 + σ(IMM16)
Assembler Syntax	`br label`
Example	`br top_of_loop`
Description	Transfers program control to the instruction at label. In the instruction encoding, the offset given by IMM16 is treated as a signed number of bytes relative to the instruction immediately following br. The two least-significant bits of IMM16 are always zero, because instruction addresses must be word-aligned.
Exceptions	Misaligned destination address
Instruction Type	I
Instruction Fields	IMM16 = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x06					

break

Instruction	debugging breakpoint
Operation	`bstatus` ← `status` PIE ← 0 U ← 0 `ba` ← PC + 4 PC ← break handler address
Assembler Syntax	`break` `break imm5`
Example	`break`
Description	Breaks program execution and transfers control to the debugger break-processing routine. Saves the address of the next instruction in register `ba` and saves the contents of the `status` register in `bstatus`. Disables interrupts, then transfers execution to the break handler. The 5-bit immediate field `imm5` is ignored by the processor, but it can be used by the debugger. `break` with no argument is the same as `break 0`.
Usage	`break` is used by debuggers exclusively. Only debuggers should place `break` in a user program, operating system, or exception handler. The address of the break handler is specified with the Nios_II Processor parameter editor in . Some debuggers support `break` and `break 0` instructions in source code. These debuggers treat the `break` instruction as a normal breakpoint.
Exceptions	Break
Instruction Type	R
Instruction Fields	`IMM5` = Type of breakpoint

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					0x1e					0x34
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x34					IMM5					0x3a					

bret

Instruction	breakpoint return
Operation	`status` ← `bstatus` PC ← `ba`
Assembler Syntax	`bret`
Example	`bret`
Description	Copies the value of `bstatus` to the `status` register, then transfers execution to the address in `ba`.
Usage	`bret` is used by debuggers exclusively and should not appear in user programs, operating systems, or exception handlers.
Exceptions	Misaligned destination address Supervisor-only instruction
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x1e					0					0x1e					0x09
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x09					0					0x3a					

call

Instruction	call subroutine

Operation	ra ← PC + 4 PC ← ($PC_{31..28}$: IMM26 x 4)
Assembler Syntax	`call label`
Example	`call write_char`
Description	Saves the address of the next instruction in register ra, and transfers execution to the instruction at address ($PC_{31..28}$: IMM26 x 4).
Usage	`call` can transfer execution anywhere within the 256-MB range determined by $PC_{31..28}$. The Nios II GNU linker does not automatically handle cases in which the address is out of this range.
Exceptions	None
Instruction Type	J
Instruction Fields	`IMM26` = 26-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IMM26															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM26										0					

callr

Instruction	call subroutine in register
Operation	ra ← PC + 4 PC ← rA
Assembler Syntax	`callr rA`
Example	`callr r6`
Description	Saves the address of the next instruction in the return address register, and transfers execution to the address contained in register rA.
Usage	`callr` is used to dereference C-language function pointers.

Exceptions	Misaligned destination address
Instruction Type	R
Instruction Fields	A = Register index of operand rA

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					0x1f					0x1d
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1d					0					0x3a					

cmpeq

Instruction	compare equal
Operation	if (rA == rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpeq rC, rA, rB`
Example	`cmpeq r6, r7, r8`
Description	If rA == rB, then stores 1 to rC; otherwise, stores 0 to rC.

Usage	`cmpeq` performs the == operation of the C programming language. Also, `cmpeq` can be used to implement the C logical negation operator "!".
	`cmpeq rC, rA, r0`
	`# Implements rC = !rA`

Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x20
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x20					0					0x3a					

cmpeqi

Instruction	compare equal immediate
Operation	if (rA == σ(IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpeqi rB, rA, IMM16`
Example	`cmpeqi r6, r7, 100`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA == σ(IMM16), `cmpeqi` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpeqi` performs the == operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x20					

cmpge

Instruction	compare greater than or equal signed
Operation	if ((signed) rA >= (signed) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpge rC, rA, rB`
Example	`cmpge r6, r7, r8`
Description	If rA >= rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpge` performs the signed >= operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x08
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x08					0					0x3a					

cmpgei

Instruction	compare greater than or equal signed immediate
Operation	if ((signed) rA >= (signed) σ(IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpgei rB, rA, IMM16`
Example	`cmpgei r6, r7, 100`

Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA >= σ(IMM16), then `cmpgei` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpgei` performs the signed >= operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x08					

cmpgeu

Instruction	compare greater than or equal unsigned
Operation	if ((unsigned) rA >= (unsigned) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpgeu rC, rA, rB`
Example	`cmpgeu r6, r7, r8`
Description	If rA >= rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpgeu` performs the unsigned >= operation of the C programming language.
Exceptions	None
Instruction Type	R

Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x28
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x28					0					0x3a					

cmpgeui

Instruction	compare greater than or equal unsigned immediate
Operation	if ((unsigned) rA >= (unsigned) (0x0000 : IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpgeui rB, rA, IMM16`
Example	`cmpgeui r6, r7, 100`
Description	Zero-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA >= (0x0000 : IMM16), then `cmpgeui` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpgeui` performs the unsigned >= operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					

Bit Fields															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x28					

cmpgt

Instruction	compare greater than signed
Operation	if ((signed) rA > (signed) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpgt rC, rA, rB`
Example	`cmpgt r6, r7, r8`
Description	If rA > rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpgt` performs the signed > operation of the C programming language.
Pseudo-instruction	`cmpgt` is implemented with the `cmplt` instruction by swapping its rA and rB operands.

cmpgti

Instruction	compare greater than signed immediate
Operation	if ((signed) rA > (signed) IMMED) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpgti rB, rA, IMMED`
Example	`cmpgti r6, r7, 100`
Description	Sign-extends the immediate value IMMED to 32 bits and compares it to the value of rA. If rA > σ(IMMED), then `cmpgti` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpgti` performs the signed > operation of the C programming language. The maximum allowed value of IMMED is 32766. The minimum allowed value is –32769.

Pseudo-instruction	`cmpgti` is implemented using a `cmpgei` instruction with an IMM16 immediate value of IMMED + 1.

cmpgtu

Instruction	compare greater than unsigned
Operation	if ((unsigned) rA > (unsigned) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpgtu rC, rA, rB`
Example	`cmpgtu r6, r7, r8`
Description	If rA > rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpgtu` performs the unsigned > operation of the C programming language.
Pseudo-instruction	`cmpgtu` is implemented with the `cmpltu` instruction by swapping its rA and rB operands.

cmpgtui

Instruction	compare greater than unsigned immediate
Operation	if ((unsigned) rA > (unsigned) IMMED) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpgtui rB, rA, IMMED`
Example	`cmpgtui r6, r7, 100`
Description	Zero-extends the immediate value IMMED to 32 bits and compares it to the value of rA. If rA > IMMED, then `cmpgtui` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpgtui` performs the unsigned > operation of the C programming language. The maximum allowed value of IMMED is 65534. The minimum allowed value is 0.

Pseudo-instruction	`cmpgtui` is implemented using a `cmpgeui` instruction with an IMM16 immediate value of IMMED + 1.

cmple

Instruction	compare less than or equal signed
Operation	if ((signed) rA <= (signed) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmple rC, rA, rB`
Example	`cmple r6, r7, r8`
Description	If rA <= rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmple` performs the signed <= operation of the C programming language.
Pseudo-instruction	`cmple` is implemented with the `cmpge` instruction by swapping its rA and rB operands.

cmplei

Instruction	compare less than or equal signed immediate
Operation	if ((signed) rA < (signed) IMMED) then rB ← 1 else rB ← 0
Assembler Syntax	`cmplei rB, rA, IMMED`
Example	`cmplei r6, r7, 100`
Description	Sign-extends the immediate value IMMED to 32 bits and compares it to the value of rA. If rA <= σ(IMMED), then `cmplei` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmplei` performs the signed <= operation of the C programming language. The maximum allowed value of IMMED is 32766. The minimum allowed value is –32769.

Pseudo-instruction	`cmplei` is implemented using a `cmplti` instruction with an IMM16 immediate value of IMMED + 1.

cmpleu

Instruction	compare less than or equal unsigned
Operation	if ((unsigned) rA < (unsigned) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpleu rC, rA, rB`
Example	`cmpleu r6, r7, r8`
Description	If rA <= rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpleu` performs the unsigned <= operation of the C programming language.
Pseudo-instruction	`cmpleu` is implemented with the `cmpgeu` instruction by swapping its rA and rB operands.

cmpleui

Instruction	compare less than or equal unsigned immediate
Operation	if ((unsigned) rA <= (unsigned) IMMED) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpleui rB, rA, IMMED`
Example	`cmpleui r6, r7, 100`
Description	Zero-extends the immediate value IMMED to 32 bits and compares it to the value of rA. If rA <= IMMED, then `cmpleui` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpleui` performs the unsigned <= operation of the C programming language. The maximum allowed value of IMMED is 65534. The minimum allowed value is 0.

Pseudo-instruction	`cmpleui` is implemented using a `cmpltui` instruction with an IMM16 immediate value of IMMED + 1.

cmplt

Instruction	compare less than signed
Operation	if ((signed) rA < (signed) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmplt rC, rA, rB`
Example	`cmplt r6, r7, r8`
Description	If rA < rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmplt` performs the signed < operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x10
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x10					0					0x3a					

cmplti

Instruction	compare less than signed immediate

Operation	if ((signed) rA < (signed) σ(IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	`cmplti rB, rA, IMM16`
Example	`cmplti r6, r7, 100`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA < σ(IMM16), then `cmplti` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmplti` performs the signed < operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x10					

cmpltu

Instruction	compare less than unsigned
Operation	if ((unsigned) rA < (unsigned) rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpltu rC, rA, rB`
Example	`cmpltu r6, r7, r8`
Description	If rA < rB, then stores 1 to rC; otherwise stores 0 to rC.

Usage	`cmpltu` performs the unsigned < operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x30
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x30					0					0x3a					

cmpltui

Instruction	compare less than unsigned immediate
Operation	if ((unsigned) rA < (unsigned) (0x0000 : IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpltui rB, rA, IMM16`
Example	`cmpltui r6, r7, 100`
Description	Zero-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA < (0x0000 : IMM16), then `cmpltui` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpltui` performs the unsigned < operation of the C programming language.
Exceptions	None
Instruction Type	I

Instruction Fields	A = Register index of operand rA B = Register index of operand rB IMM16 = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x30					

cmpne

Instruction	compare not equal
Operation	if (rA != rB) then rC ← 1 else rC ← 0
Assembler Syntax	`cmpne rC, rA, rB`
Example	`cmpne r6, r7, r8`
Description	If rA != rB, then stores 1 to rC; otherwise stores 0 to rC.
Usage	`cmpne` performs the != operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x18

Bit Fields		
0x18	0	0x3a

cmpnei

Instruction	compare not equal immediate
Operation	if (rA != σ(IMM16)) then rB ← 1 else rB ← 0
Assembler Syntax	`cmpnei rB, rA, IMM16`
Example	`cmpnei r6, r7, 100`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and compares it to the value of rA. If rA != σ(IMM16), then `cmpnei` stores 1 to rB; otherwise stores 0 to rB.
Usage	`cmpnei` performs the != operation of the C programming language.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x18					

custom

Instruction	custom instruction

Operation	if writerc == 1 then rC ← f_N(rA, rB, A, B, C) else Ø ← f_N(rA, rB, A, B, C)
Assembler Syntax	`custom N, xC, xA, xB` Where xA means either general purpose register rA, or custom register cA.
Example	`custom 0, c6, r7, r8`
Description	The `custom` opcode provides access to up to 256 custom instructions allowed by the Nios II architecture. The function implemented by a custom instruction is user-defined and is specified with the Nios_II Processor parameter editor in . The 8-bit immediate N field specifies which custom instruction to use. Custom instructions can use up to two parameters, xA and xB, and can optionally write the result to a register xC.
Usage	To access a custom register inside the custom instruction logic, clear the bit readra, readrb, or writerc that corresponds to the register field. In assembler syntax, the notation cN refers to register N in the custom register file and causes the assembler to clear the c bit of the opcode. For example, `custom 0, c3, r5, r0` performs custom instruction 0, operating on general-purpose registers r5 and r0, and stores the result in custom register 3.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand A `B` = Register index of operand B `C` = Register index of operand C `readra` = 1 if instruction uses rA, 0 otherwise `readrb` = 1 if instruction uses rB, 0 otherwise `writerc` = 1 if instruction provides result for rC, 0 otherwise `N` = 8-bit number that selects instruction

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					readra
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Fields			
readrb	writerc	N	0x32

div

Instruction	divide
Operation	rC ← rA ÷ rB
Assembler Syntax	`div rC, rA, rB`
Example	`div r6, r7, r8`
Description	Treating rA and rB as signed integers, this instruction divides rA by rB and then stores the integer portion of the resulting quotient to rC. After attempted division by zero, the value of rC is undefined. There is no divide-by-zero exception. After dividing –2147483648 by –1, the value of rC is undefined (the number +2147483648 is not representable in 32 bits). There is no overflow exception. processors that do not implement the `div` instruction cause an unimplemented instruction exception.

Usage	Remainder of Division:
	If the result of the division is defined, then the remainder can be computed in rD using the following instruction sequence:
	`div rC, rA, rB`
	`mul rD, rC, rB`
	`sub rD, rA, rD`
	`# The original div operation`
	`# rD = remainder`

Exceptions	Division error Unimplemented instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x25					0					0x3a					

divu

Instruction	divide unsigned
Operation	rC ← rA ÷ rB
Assembler Syntax	`divu rC, rA, rB`
Example	`divu r6, r7, r8`
Description	Treating rA and rB as unsigned integers, this instruction divides rA by rB and then stores the integer portion of the resulting quotient to rC. After attempted division by zero, the value of rC is undefined. There is no divide-by-zero exception. processors that do not implement the `divu` instruction cause an unimplemented instruction exception.

Usage	Remainder of Division:
	If the result of the division is defined, then the remainder can be computed in rD using the following instruction sequence:
	`divu rC, rA, rB`
	`mul rD, rC, rB`
	`sub rD, rA, rD`
	`# The original divu operation`
	`# rD = remainder`

Exceptions	Division error Unimplemented instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x24
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x24					0					0x3a					

eret

Instruction	exception return
Operation	`status ← estatus` PC ← `ea`
Assembler Syntax	`eret`
Example	`eret`
Description	Copies the value of `estatus` into the `status` register, and transfers execution to the address in `ea`.
Usage	Use `eret` to return from traps, external interrupts, and other exception handling routines. Note that before returning from hardware interrupt exceptions, the exception handler must adjust the `ea` register.
Exceptions	Misaligned destination address Supervisor-only instruction
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x1d					0x1e					C					0x01
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x01					0					0x3a					

flushd

Instruction	flush data cache line

Operation	Flushes the data cache line associated with address rA + σ(IMM16).
Assembler Syntax	`flushd IMM16(rA)`
Example	`flushd -100(r6)`
Description	If the processor implements a direct mapped data cache, `flushd` writes the data cache line that is mapped to the specified address back to memory if the line is dirty, and then clears the data cache line. Unlike `flushda`, `flushd` writes the dirty data back to memory even when the addressed data is not currently in the cache. This process comprises the following steps: • Compute the effective address specified by the sum of rA and the signed 16-bit immediate value. • Identify the data cache line associated with the computed effective address. Each data cache effective address comprises a `tag` field and a `line` field. When identifying the data cache line, `flushd` ignores the `tag` field and only uses the `line` field to select the data cache line to clear. • Skip comparing the cache line tag with the effective address to determine if the addressed data is currently cached. Because `flushd` ignores the cache line tag, `flushd` flushes the cache line regardless of whether the specified data location is currently cached. • If the data cache line is dirty, write the line back to memory. A cache line is dirty when one or more words of the cache line have been modified by the processor, but are not yet written to memory. • Clear the valid bit for the line. If the processor core does not have a data cache, the `flushd` instruction performs no operation.
Usage	Use `flushd` to write dirty lines back to memory even if the addressed memory location is not in the cache, and then flush the cache line. By contrast, refer to "flushda flush data cache address", "initd initialize data cache line", and "initda initialize data cache address" for other cache-clearing options. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					IMM16

flushda

Instruction	flush data cache address
Operation	Flushes the data cache line currently caching address rA + σ(IMM16)
Assembler Syntax	`flushda IMM16(rA)`
Example	`flushda -100(r6)`

Description	If the processor implements a direct mapped data cache, `flushda` writes the data cache line that is mapped to the specified address back to memory if the line is dirty, and then clears the data cache line. Unlike `flushd`, `flushda` writes the dirty data back to memory only when the addressed data is currently in the cache. This process comprises the following steps: • Compute the effective address specified by the sum of rA and the signed 16-bit immediate value. • Identify the data cache line associated with the computed effective address. Each data cache effective address comprises a `tag` field and a `line` field. When identifying the line, `flushda` uses both the `tag` field and the `line` field. • Compare the cache line tag with the effective address to determine if the addressed data is currently cached. If the `tag` fields do not match, the effective address is not currently cached, so the instruction does nothing. • If the data cache line is dirty and the `tag` fields match, write the dirty cache line back to memory. A cache line is dirty when one or more words of the cache line have been modified by the processor, but are not yet written to memory. • Clear the valid bit for the line. If the processor core does not have a data cache, the `flushda` instruction performs no operation.
Usage	Use `flushda` to write dirty lines back to memory only if the addressed memory location is currently in the cache, and then flush the cache line. By contrast, refer to "flushd flush data cache line", "initd initialize data cache line", and "initda initialize data cache address" for other cache-clearing options. For more information on the Nios II data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	Supervisor-only data address Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `IMM16` = 16-bit signed immediate value

Cache and Tightly-Coupled Memory

flushp

Instruction	flush pipeline
Operation	Flushes the processor pipeline of any prefetched instructions.
Assembler Syntax	`flushp`
Example	`flushp`
Description	Ensures that any instructions prefetched after the `flushp` instruction are removed from the pipeline.
Usage	Use `flushp` before transferring control to newly updated instruction memory.
Exceptions	None
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					0					0x04

0x04					0					0x3a					

initd

Instruction	initialize data cache line
Operation	Initializes the data cache line associated with address rA + σ(IMM16).
Assembler Syntax	`initd IMM16(rA)`
Example	`initd 0(r6)`

Description	If the processor implements a direct mapped data cache, `initd` clears the data cache line without checking for (or writing) a dirty data cache line that is mapped to the specified address back to memory. Unlike `initda`, `initd` clears the cache line regardless of whether the addressed data is currently cached. This process comprises the following steps: • Compute the effective address specified by the sum of rA and the signed 16-bit immediate value. • Identify the data cache line associated with the computed effective address. Each data cache effective address comprises a `tag` field and a `line` field. When identifying the line, `initd` ignores the `tag` field and only uses the `line` field to select the data cache line to clear. • Skip comparing the cache line tag with the effective address to determine if the addressed data is currently cached. Because `initd` ignores the cache line tag, `initd` flushes the cache line regardless of whether the specified data location is currently cached. • Skip checking if the data cache line is dirty. Because `initd` skips the dirty cache line check, data that has been modified by the processor, but not yet written to memory is lost. • Clear the valid bit for the line. If the processor core does not have a data cache, the `initd` instruction performs no operation.
Usage	Use `initd` after processor reset and before accessing data memory to initialize the processor's data cache. Use `initd` with caution because it does not write back dirty data. By contrast, refer to "flushd flush data cache line", "flushda flush data cache address", and "initda initialize data cache address" for other cache-clearing options. recommends using `initd` only when the processor comes out of reset. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	Supervisor-only instruction
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `IMM16` = 16-bit signed immediate value

initda

Instruction	initialize data cache address
Operation	Initializes the data cache line currently caching address rA + σ(IMM16)
Assembler Syntax	`initda IMM16(rA)`
Example	`initda -100(r6)`
Description	If the processor implements a direct mapped data cache, `initda` clears the data cache line without checking for (or writing) a dirty data cache line that is mapped to the specified address back to memory. Unlike `initd`, `initda` clears the cache line only when the addressed data is currently cached. This process comprises the following steps: • Compute the effective address specified by the sum of rA and the signed 16-bit immediate value. • Identify the data cache line associated with the computed effective address. Each data cache effective address comprises a `tag` field and a `line` field. When identifying the line, `initda` uses both the `tag` field and the `line` field. • Compare the cache line tag with the effective address to determine if the addressed data is currently cached. If the `tag` fields do not match, the effective address is not currently cached, so the instruction does nothing. • Skip checking if the data cache line is dirty. Because `initd` skips the dirty cache line check, data that has been modified by the processor, but not yet written to memory is lost. • Clear the valid bit for the line. If the processor core does not have a data cache, the `initda` instruction performs no operation.

Usage	Use `initda` to skip writing dirty lines back to memory and to flush the cache line only if the addressed memory location is currently in the cache. By contrast, refer to "flushd flush data cache line", "flushda flush data cache address", and "initd initialize data cache line" on page 8–55 for other cache-clearing options. Use `initda` with caution because it does not write back dirty data. For more information on the Nios II data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	Supervisor-only data address Fast TLB miss (data) Double TLB miss (data) MPU region violation (data) Unimplemented instruction

initi

Instruction	initialize instruction cache line
Operation	Initializes the instruction cache line associated with address rA.
Assembler Syntax	`initi rA`

Example	`initi r6`
Description	Ignoring the tag, `initi` identifies the instruction cache line associated with the byte address in `ra`, and `initi` invalidates that line. If the processor core does not have an instruction cache, the `initi` instruction performs no operation.
Usage	This instruction is used to initialize the processor's instruction cache. Immediately after processor reset, use `initi` to invalidate each line of the instruction cache. For more information on instruction cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	Supervisor-only instruction
Instruction Type	R
Instruction Fields	A = Register index of operand rA

Cache and Tightly-Coupled Memory

jmp

Instruction	computed jump
Operation	PC ← rA
Assembler Syntax	`jmp rA`
Example	`jmp r12`
Description	Transfers execution to the address contained in register rA.

Usage	It is illegal to jump to the address contained in register r31. To return from subroutines called by `call` or `callr`, use `ret` instead of `jmp`.
Exceptions	Misaligned destination address
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0x0d					0					0x3a					

jmpi

Instruction	jump immediate
Operation	PC ← ($PC_{31..28}$: IMM26 x 4)
Assembler Syntax	`jmpi label`
Example	`jmpi write_char`
Description	Transfers execution to the instruction at address ($PC_{31..28}$: IMM26 x 4).
Usage	`jmpi` is a low-overhead local jump. `jmpi` can transfer execution anywhere within the 256-MB range determined by $PC_{31..28}$. The Nios II GNU linker does not automatically handle cases in which the address is out of this range.
Exceptions	None
Instruction Type	J
Instruction Fields	`IMM26` = 26-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ldb / ldbio

Instruction	load byte from memory or I/O peripheral
Operation	rB ← σ(Mem8[rA + σ(IMM16)])
Assembler Syntax	`ldb rB, byte_offset(rA)` `ldbio rB, byte_offset(rA)`
Example	`ldb r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the desired memory byte, sign extending the 8-bit value to 32 bits. In processor cores with a data cache, this instruction may retrieve the desired data from the cache instead of from memory.
Usage	Use the `ldbio` instruction for peripheral I/O. In processors with a data cache, `ldbio` bypasses the cache and is guaranteed to generate an -MM data transfer. In processors without a data cache, `ldbio` acts like `ldb`. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (read) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Cache and Tightly-Coupled Memory

ldbu / ldbuio

Instruction	load unsigned byte from memory or I/O peripheral
Operation	rB ← 0x000000 : Mem8[rA + σ(IMM16)]
Assembler Syntax	`ldbu rB, byte_offset(rA)` `ldbuio rB, byte_offset(rA)`
Example	`ldbu r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the desired memory byte, zero extending the 8-bit value to 32 bits.
Usage	In processors with a data cache, this instruction may retrieve the desired data from the cache instead of from memory. Use the `ldbuio` instruction for peripheral I/O. In processors with a data cache, `ldbuio` bypasses the cache and is guaranteed to generate an -MM data transfer. In processors without a data cache, `ldbuio` acts like `ldbu`. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (read) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)

Operation	rB ← σ(Mem16[rA + σ(IMM16)])
Assembler Syntax	`ldh rB, byte_offset(rA)` `ldhio rB, byte_offset(rA)`

Example	`ldh r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the memory halfword located at the effective byte address, sign extending the 16-bit value to 32 bits. The effective byte address must be halfword aligned. If the byte address is not a multiple of 2, the operation is undefined.
Usage	In processors with a data cache, this instruction may retrieve the desired data from the cache instead of from memory. Use the `ldhio` instruction for peripheral I/O. In processors with a data cache, `ldhio` bypasses the cache and is guaranteed to generate an -MM data transfer. In processors without a data cache, `ldhio` acts like `ldh`. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.
Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (read) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Related Information

Cache and Tightly-Coupled Memory

ldhu / ldhuio

Instruction	load unsigned halfword from memory or I/O peripheral
Operation	rB ← 0x0000 : Mem16[rA + σ(IMM16)]
Assembler Syntax	`ldhu rB, byte_offset(rA)` `ldhuio rB, byte_offset(rA)`
Example	`ldhu r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the memory halfword located at the effective byte address, zero extending the 16-bit value to 32 bits. The effective byte address must be halfword aligned. If the byte address is not a multiple of 2, the operation is undefined.
Usage	In processors with a data cache, this instruction may retrieve the desired data from the cache instead of from memory. Use the `ldhuio` instruction for peripheral I/O. In processors with a data cache, `ldhuio` bypasses the cache and is guaranteed to generate an -MM data transfer. In processors without a data cache, `ldhuio` acts like `ldhu`. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (read) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Cache and Tightly-Coupled Memory

ldw / ldwio

Instruction	load 32-bit word from memory or I/O peripheral
Operation	rB ← Mem32[rA + σ(IMM16)]
Assembler Syntax	`ldw rB, byte_offset(rA)` `ldwio rB, byte_offset(rA)`

Example	`ldw r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Loads register rB with the memory word located at the effective byte address. The effective byte address must be word aligned. If the byte address is not a multiple of 4, the operation is undefined.
Usage	In processors with a data cache, this instruction may retrieve the desired data from the cache instead of from memory. Use the `ldwio` instruction for peripheral I/O. In processors with a data cache, `ldwio` bypasses the cache and memory. Use the `ldwio` instruction for peripheral I/O. In processors with a data cache, `ldwio` bypasses the cache and is guaranteed to generate an -MM data transfer. In processors without a data cache, `ldwio` acts like `ldw`. For more information on data cache, refer to the *Cache and Tightly Coupled Memory* chapter of the *Nios II Software Developer's Handbook*.

Related Information

Cache and Tightly-Coupled Memory

mov

Instruction	move register to register
Operation	rC ← rA
Assembler Syntax	`mov rC, rA`
Example	`mov r6, r7`
Description	Moves the contents of rA to rC.
Pseudo-instruction	`mov` is implemented as `add rC, rA, r0`.

movhi

Instruction	move immediate into high halfword
Operation	rB ← (IMMED : 0x0000)
Assembler Syntax	`movhi rB, IMMED`
Example	`movhi r6, 0x8000`
Description	Writes the immediate value IMMED into the high halfword of rB, and clears the lower halfword of rB to 0x0000.

Usage	The maximum allowed value of IMMED is 65535. The minimum allowed value is 0. To load a 32-bit constant into a register, first load the upper 16 bits using a `movhi` pseudo-instruction. The `%hi()` macro can be used to extract the upper 16 bits of a constant or a label. Then, load the lower 16 bits with an `ori` instruction. The `%lo()` macro can be used to extract the lower 16 bits of a constant or label as shown in the following code:
	`movhi rB, %hi(value)`
	`ori rB, rB, %lo(value)`
	An alternative method to load a 32-bit constant into a register uses the %hiadj() macro and the `addi` instruction as shown in the following code:
	`movhi rB, %hiadj(value)`
	`addi rB, rB, %lo(value)`

Pseudo-instruction	`movhi` is implemented as `orhi rB, r0, IMMED`.

movi

Instruction	move signed immediate into word
Operation	rB ← σ(IMMED)
Assembler Syntax	`movi rB, IMMED`
Example	`movi r6, -30`
Description	Sign-extends the immediate value IMMED to 32 bits and writes it to rB.
Usage	The maximum allowed value of IMMED is 32767. The minimum allowed value is –32768. To load a 32-bit constant into a register, refer to the `movhi` instruction.
Pseudo-instruction	`movi` is implemented as `addi rB, r0, IMMED`.

movia

Instruction	move immediate address into word
Operation	rB ← label

Assembler Syntax	`movia rB, label`
Example	`movia r6, function_address`
Description	Writes the address of label to rB.

Pseudo-instruction	`movia` is implemented as:
	`orhi rB, r0, %hiadj(label)`
	`addi rB, rB, %lo(label)`

movui

Instruction	move unsigned immediate into word
Operation	rB ← (0x0000 : IMMED)
Assembler Syntax	`movui rB, IMMED`
Example	`movui r6, 100`
Description	Zero-extends the immediate value IMMED to 32 bits and writes it to rB.
Usage	The maximum allowed value of IMMED is 65535. The minimum allowed value is 0. To load a 32-bit constant into a register, refer to the `movhi` instruction.
Pseudo-instruction	`movui` is implemented as `ori rB, r0, IMMED`.

mul

Instruction	multiply
Operation	rC ← (rA x rB) $_{31..0}$
Assembler Syntax	`mul rC, rA, rB`
Example	`mul r6, r7, r8`
Description	Multiplies rA times rB and stores the 32 low-order bits of the product to rC. The result is the same whether the operands are treated as signed or unsigned integers. processors that do not implement the `mul` instruction cause an unimplemented instruction exception.

Usage	Carry Detection (unsigned operands):
	Before or after the multiply operation, the carry out of the MSB of rC can be detected using the following instruction sequence:
	`mul rC, rA, rB`
	`mulxuu rD, rA, rB`
	`cmpne rD, rD, r0`
	`# The mul operation (optional)`
	`# rD is nonzero if carry occurred`
	`# rD is 1 if carry occurred, 0 if not`
	The `mulxuu` instruction writes a nonzero value into rD if the multiplication of unsigned numbers generates a carry (unsigned overflow). If a 0/1 result is desired, follow the `mulxuu` with the `cmpne` instruction.
	Overflow Detection (signed operands):
	After the multiply operation, overflow can be detected using the following instruction sequence:
	`mul rC, rA, rB`
	`cmplt rD, rC, r0`
	`mulxss rE, rA, rB`
	`add rD, rD, rE`
	`cmpne rD, rD, r0`
	`# The original mul operation`
	`# rD is nonzero if overflow`
	`# rD is 1 if overflow, 0 if not`
	The `cmplt-mulxss-add` instruction sequence writes a nonzero value into rD if the product in rC cannot be represented in 32 bits (signed overflow). If a 0/1 result is desired, follow the instruction sequence with the `cmpne` instruction.

Exceptions	Unimplemented instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x27					0					0x3a					

muli

Instruction	multiply immediate
Operation	rB ← (rA x σ(IMM16)) $_{31..0}$
Assembler Syntax	`muli rB, rA, IMM16`
Example	`muli r6, r7, -100`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits and multiplies it by the value of rA. Stores the 32 low-order bits of the product to rB. The result is independent of whether rA is treated as a signed or unsigned number. processors that do not implement the `muli` instruction cause an unimplemented instruction exception. Carry Detection and Overflow Detection: For a discussion of carry and overflow detection, refer to the `mul` instruction.
Exceptions	Unimplemented instruction
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IMM16										0x24					

mulxss

Instruction	multiply extended signed/signed
Operation	rC ← ((signed) rA) x ((signed) rB)) $_{63..32}$
Assembler Syntax	`mulxss rC, rA, rB`
Example	`mulxss r6, r7, r8`
Description	Treating rA and rB as signed integers, `mulxss` multiplies rA times rB, and stores the 32 high-order bits of the product to rC. processors that do not implement the `mulxss` instruction cause an unimplemented instruction exception.
Usage	Use `mulxss` and `mul` to compute the full 64-bit product of two 32-bit signed integers. Furthermore, `mulxss` can be used as part of the calculation of a 128-bit product of two 64-bit signed integers. Given two 64-bit integers, each contained in a pair of 32-bit registers, (S1 : U1) and (S2 : U2), their 128-bit product is (U1 x U2) + ((S1 x U2) << 32) + ((U1 x S2) << 32) + ((S1 x S2) << 64). The `mulxss` and `mul` instructions are used to calculate the 64-bit product S1 x S2.
Exceptions	Unimplemented instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1f					0					0x3a					

mulxsu

Instruction	multiply extended signed/unsigned
Operation	rC ← ((signed) rA) x ((unsigned) rB)) $_{63..32}$

Assembler Syntax	`mulxsu rC, rA, rB`
Example	`mulxsu r6, r7, r8`
Description	Treating rA as a signed integer and rB as an unsigned integer, `mulxsu` multiplies rA times rB, and stores the 32 high-order bits of the product to rC. processors that do not implement the `mulxsu` instruction cause an unimplemented instruction exception.
Usage	`mulxsu` can be used as part of the calculation of a 128-bit product of two 64-bit signed integers. Given two 64-bit integers, each contained in a pair of 32-bit registers, (S1 : U1) and (S2 : U2), their 128-bit product is: (U1 x U2) + ((S1 x U2) << 32) + ((U1 x S2) << 32) + ((S1 x S2) << 64). The `mulxsu` and `mul` instructions are used to calculate the two 64-bit products S1 x U2 and U1 x S2.
Exceptions	Unimplemented instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x17
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x17					0					0x3a					

mulxuu

Instruction	multiply extended unsigned/unsigned
Operation	rC ← ((unsigned) rA) x ((unsigned) rB)) $_{63..32}$
Assembler Syntax	`mulxuu rC, rA, rB`
Example	`mulxuu r6, r7, r8`

Description	Treating rA and rB as unsigned integers, `mulxuu` multiplies rA times rB and stores the 32 high-order bits of the product to rC. processors that do not implement the `mulxuu` instruction cause an unimplemented instruction exception.
Usage	Use `mulxuu` and `mul` to compute the 64-bit product of two 32-bit unsigned integers. Furthermore, `mulxuu` can be used as part of the calculation of a 128-bit product of two 64-bit signed integers. Given two 64-bit signed integers, each contained in a pair of 32-bit registers, (S1 : U1) and (S2 : U2), their 128-bit product is (U1 x U2) + ((S1 x U2) << 32) + ((U1 x S2) << 32) + ((S1 x S2) << 64). The `mulxuu` and `mul` instructions are used to calculate the 64-bit product U1 x U2. `mulxuu` also can be used as part of the calculation of a 128-bit product of two 64-bit unsigned integers. Given two 64-bit unsigned integers, each contained in a pair of 32-bit registers, (T1 : U1) and (T2 : U2), their 128-bit product is (U1 x U2) + ((U1 x T2) << 32) + ((T1 x U2) << 32) + ((T1 x T2) << 64). The `mulxuu` and `mul` instructions are used to calculate the four 64-bit products U1 x U2, U1 x T2, T1 x U2, and T1 x T2.
Exceptions	Unimplemented instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0x07					0					0x3a					

nextpc

Instruction	get address of following instruction
Operation	rC ← PC + 4
Assembler Syntax	`nextpc rC`
Example	`nextpc r6`

Description	Stores the address of the next instruction to register rC.
Usage	A relocatable code fragment can use `nextpc` to calculate the address of its data segment. `nextpc` is the only way to access the PC directly.
Exceptions	None
Instruction Type	R
Instruction Fields	`C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0x1c					0					0x3a					

nop

Instruction	no operation
Operation	None
Assembler Syntax	`nop`
Example	`nop`
Description	`nop` does nothing.
Pseudo-instruction	`nop` is implemented as `add r0, r0, r0`.

nor

Instruction	bitwise logical nor
Operation	rC ← ~(rA | rB)
Assembler Syntax	`nor rC, rA, rB`
Example	`nor r6, r7, r8`

Description	Calculates the bitwise logical NOR of rA and rB and stores the result in rC.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	A					B					C					0x06						0					0x3a					

or

Instruction	bitwise logical or
Operation	rC ← rA | rB
Assembler Syntax	`or rC, rA, rB`
Example	`or r6, r7, r8`
Description	Calculates the bitwise logical OR of rA and rB and stores the result in rC.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields

0x16					0					0x3a					

orhi

Instruction	bitwise logical or immediate into high halfword
Operation	rB ← rA | (IMM16 : 0x0000)
Assembler Syntax	`orhi rB, rA, IMM16`
Example	`orhi r6, r7, 100`
Description	Calculates the bitwise logical OR of rA and (IMM16 : 0x0000) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16

ori

Instruction	bitwise logical or immediate
Operation	rB ← rA | (0x0000 : IMM16)
Assembler Syntax	`ori rB, rA, IMM16`
Example	`ori r6, r7, 100`
Description	Calculates the bitwise logical OR of rA and (0x0000 : IMM16) and stores the result in rB.
Exceptions	None
Instruction Type	I

Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IMM16										0x14					

rdctl

Instruction	read from control register
Operation	rC ← ctlN
Assembler Syntax	`rdctl rC, ctlN`
Example	`rdctl r3, ctl31`
Description	Reads the value contained in control register ctlN and writes it to register rC.
Exceptions	Supervisor-only instruction
Instruction Type	R
Instruction Fields	`C` = Register index of operand rC `N` = Control register index of operand ctlN

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					C					0x26
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x26					N					0x3a					

rdprs

Instruction	read from previous register set

Operation	rB ← prs.rA + σ(IMM16)
Assembler Syntax	`rdprs rB, rA, IMM16`
Example	`rdprs r6, r7, 0`
Description	Sign-extends the 16-bit immediate value IMM16 to 32 bits, and adds it to the value of rA from the previous register set. Places the result in rB in the current register set.
Usage	The previous register set is specified by status.PRS. By default, status.PRS indicates the register set in use before an exception, such as an external interrupt, caused a register set change. To read from an arbitrary register set, software can insert the desired register set number in `status.PRS` prior to executing `rdprs`. If shadow register sets are not implemented on the Nios II core, `rdprs` is an illegal instruction.
Exceptions	Supervisor-only instruction Illegal instruction
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x38					

ret

Instruction	return from subroutine
Operation	PC ← `ra`
Assembler Syntax	`ret`
Example	`ret`

Description	Transfers execution to the address in `ra`.
Usage	Any subroutine called by `call` or `callr` must use `ret` to return.
Exceptions	Misaligned destination address
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0x1f					0					0					0x05
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x05					0					0x3a					

rol

Instruction	rotate left
Operation	rC ← rA rotated left $rB_{4..0}$ bit positions
Assembler Syntax	`rol rC, rA, rB`
Example	`rol r6, r7, r8`
Description	Rotates rA left by the number of bits specified in $rB_{4..0}$ and stores the result in rC. The bits that shift out of the register rotate into the least-significant bit positions. Bits 31–5 of rB are ignored.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x03

Bit Fields															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x03					0					0x3a					

roli

Instruction	rotate left immediate
Operation	rC ← rA rotated left IMM5 bit positions
Assembler Syntax	`roli rC, rA, IMM5`
Example	`roli r6, r7, 3`
Description	Rotates rA left by the number of bits specified in IMM5 and stores the result in rC. The bits that shift out of the register rotate into the least-significant bit positions.
Usage	In addition to the rotate-left operation, roli can be used to implement a rotate-right operation. Rotating left by (32 – IMM5) bits is the equivalent of rotating right by IMM5 bits.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `C` = Register index of operand rC `IMM5` = 5-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x02					IMM5					0x3a					

ror

Instruction	rotate right
Operation	rC ← rA rotated right $rB_{4..0}$ bit positions

Assembler Syntax	`ror rC, rA, rB`
Example	`ror r6, r7, r8`
Description	Rotates rA right by the number of bits specified in $rB_{4..0}$ and stores the result in rC. The bits that shift out of the register rotate into the most-significant bit positions. Bits 31– 5 of rB are ignored.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x0b
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0b					0					0x3a					

sll

Instruction	shift left logical
Operation	rC ← rA << ($rB_{4..0}$)
Assembler Syntax	`sll rC, rA, rB`
Example	`sll r6, r7, r8`
Description	Shifts rA left by the number of bits specified in $rB_{4..0}$ (inserting zeroes), and then stores the result in rC. `sll` performs the << operation of the C programming language.
Exceptions	None
Instruction Type	R

Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x13
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x13					0					0x3a					

slli

Instruction	shift left logical immediate
Operation	rC ← rA << IMM5
Assembler Syntax	`slli rC, rA, IMM5`
Example	`slli r6, r7, 3`
Description	Shifts rA left by the number of bits specified in IMM5 (inserting zeroes), and then stores the result in rC.
Usage	`slli` performs the << operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	A = Register index of operand rA C = Register index of operand rC IMM5 = 5-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					C					0x12
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x12					IMM5					0x3a					

sra

Instruction	shift right arithmetic
Operation	rC ← (signed) rA >> ((unsigned) $rB_{4..0}$)
Assembler Syntax	`sra rC, rA, rB`
Example	`sra r6, r7, r8`
Description	Shifts rA right by the number of bits specified in $rB_{4..0}$ (duplicating the sign bit), and then stores the result in rC. Bits 31–5 are ignored.
Usage	`sra` performs the signed >> operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x3b
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x3b					0					0x3a					

srai

Instruction	shift right arithmetic immediate
Operation	rC ← (signed) rA >> ((unsigned) IMM5)
Assembler Syntax	`srai rC, rA, IMM5`
Example	`srai r6, r7, 3`
Description	Shifts rA right by the number of bits specified in IMM5 (duplicating the sign bit), and then stores the result in rC.

Usage	`srai` performs the signed >> operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `C` = Register index of operand rC `IMM5` = 5-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					C					0x3a
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x3a					IMM5					0x3a					

srl

Instruction	shift right logical
Operation	rC ← (unsigned) rA >> ((unsigned) $rB_{4..0}$)
Assembler Syntax	`srl rC, rA, rB`
Example	`srl r6, r7, r8`
Description	Shifts rA right by the number of bits specified in $rB_{4..0}$ (inserting zeroes), and then stores the result in rC. Bits 31–5 are ignored.
Usage	`srl` performs the unsigned >> operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x1b
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1b					0					0x3a					

srli

Instruction	shift right logical immediate
Operation	rC ← (unsigned) rA >> ((unsigned) IMM5)
Assembler Syntax	`srli rC, rA, IMM5`
Example	`srli r6, r7, 3`
Description	Shifts rA right by the number of bits specified in IMM5 (inserting zeroes), and then stores the result in rC.
Usage	`srli` performs the unsigned >> operation of the C programming language.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `C` = Register index of operand rC `IMM5` = 5-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x1a
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1a					IMM5					0x3a					

stb / stbio l

Instruction	store byte to memory or I/O periphera
Operation	Mem8[rA + σ(IMM16)] ← $rB_{7..0}$

Assembler Syntax	`stb rB, byte_offset(rA)` `stbio rB, byte_offset(rA)`
Example	`stb r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Stores the low byte of rB to the memory byte specified by the effective address.
Usage	In processors with a data cache, this instruction may not generate an -MM bus cycle to noncache data memory immediately. Use the `stbio` instruction for peripheral I/O. In processors with a data cache, `stbio` bypasses the cache and is guaranteed to generate an -MM data transfer. In processors without a data cache, `stbio` acts like `stb`.
Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (write) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Table 8-19: stb

Bit Fields

IMM16										0x25					

sth / sthio

Instruction	store halfword to memory or I/O peripheral
Operation	Mem16[rA + σ(IMM16)] ← $rB_{15..0}$
Assembler Syntax	`sth rB, byte_offset(rA)` `sthio rB, byte_offset(rA)`
Example	`sth r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Stores the low halfword of rB to the memory location specified by the effective byte address. The effective byte address must be halfword aligned. If the byte address is not a multiple of 2, the operation is undefined.
Usage	In processors with a data cache, this instruction may not generate an -MM data transfer immediately. Use the sthio instruction for peripheral I/O. In processors with a data cache, `sthio` bypasses the cache and is guaranteed to generate an -MM data transfer. In processors without a data cache, `sthio` acts like `sth`.
Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (write) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

Table 8-21: sth

IMM16										0x2d					

stw / stwio

Instruction	store word to memory or I/O peripheral
Operation	Mem32[rA + σ(IMM16)] ← rB
Assembler Syntax	`stw rB, byte_offset(rA)` `stwio rB, byte_offset(rA)`
Example	`stw r6, 100(r5)`
Description	Computes the effective byte address specified by the sum of rA and the instruction's signed 16-bit immediate value. Stores rB to the memory location specified by the effective byte address. The effective byte address must be word aligned. If the byte address is not a multiple of 4, the operation is undefined.
Usage	In processors with a data cache, this instruction may not generate an -MM data transfer immediately. Use the `stwio` instruction for peripheral I/O. In processors with a data cache, `stwio` bypasses the cache and is guaranteed to generate an -MM bus cycle. In processors without a data cache, `stwio` acts like `stw`.

Exceptions	Supervisor-only data address Misaligned data address TLB permission violation (write) Fast TLB miss (data) Double TLB miss (data) MPU region violation (data)
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit signed immediate value

IMM16										0x35					

sub

Instruction	subtract
Operation	rC ← rA – rB
Assembler Syntax	`sub rC, rA, rB`
Example	`sub r6, r7, r8`
Description	Subtract rB from rA and store the result in rC.

Usage	Carry Detection (unsigned operands):
	The carry bit indicates an unsigned overflow. Before or after a sub operation, a carry out of the MSB can be detected by checking whether the first operand is less than the second operand. The carry bit can be written to a register, or a conditional branch can be taken based on the carry condition. Both cases are shown in the following code:
	`sub rC, rA, rB`
	`cmpltu rD, rA, rB`
	`sub rC, rA, rB`
	`bltu rA, rB, label`
	`# The original sub operation (optional)`
	`# rD is written with the carry bit`
	`# The original sub operation (optional)`
	`# Branch if carry generated`
	Overflow Detection (signed operands):
	Detect overflow of signed subtraction by comparing the sign of the difference that is written to rC with the signs of the operands. If rA and rB have different signs, and the sign of rC is different than the sign of rA, an overflow occurred. The overflow condition can control a conditional branch, as shown in the following code:
	`sub rC, rA, rB`
	`xor rD, rA, rB`
	`xor rE, rA, rC`
	`and rD, rD, rE`
	`blt rD, r0, label`
	`# The original sub operation`
	`# Compare signs of rA and rB`
	`# Compare signs of rA and rC`
	`# Combine comparisons`
	`# Branch if overflow occurred`

Exceptions	None
Instruction Type	R

Instruction Fields	A = Register index of operand rA B = Register index of operand rB C = Register index of operand rC

Bit Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x39					0					0x3a					

subi

Instruction	subtract immediate
Operation	rB ← rA – σ(IMMED)
Assembler Syntax	`subi rB, rA, IMMED`
Example	`subi r8, r8, 4`
Description	Sign-extends the immediate value IMMED to 32 bits, subtracts it from the value of rA and then stores the result in rB.
Usage	The maximum allowed value of IMMED is 32768. The minimum allowed value is –32767.
Pseudo-instruction	`subi` is implemented as `addi rB, rA, -IMMED`

sync

Instruction	memory synchronization
Operation	None
Assembler Syntax	`sync`
Example	`sync`

Description	Forces all pending memory accesses to complete before allowing execution of subsequent instructions. In processor cores that support in-order memory accesses only, this instruction performs no operation.
Exceptions	None
Instruction Type	R
Instruction Fields	None

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					0					0x36
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x36					0					0x3a					

trap

Instruction	trap
Operation	`estatus` ← `status` PIE ← 0 U ← 0 ea ← PC + 4 PC ← exception handler address
Assembler Syntax	`trap` `trap imm5`
Example	`trap`
Description	Saves the address of the next instruction in register `ea`, saves the contents of the `status` register in `estatus`, disables interrupts, and transfers execution to the exception handler. The address of the exception handler is specified with the Nios_II Processor parameter editor in . The 5-bit immediate field `imm5` is ignored by the processor, but it can be used by the debugger. `trap` with no argument is the same as `trap 0`.

Usage	To return from the exception handler, execute an `eret` instruction.
Exceptions	Trap
Instruction Type	R
Instruction Fields	`IMM5` = Type of breakpoint

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					0					0x1d					0x2d
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x2d					IMM5					0x3a					

wrctl

Instruction	write to control register
Operation	ctlN ← rA
Assembler Syntax	`wrctl ctlN, rA`
Example	`wrctl ctl6, r3`
Description	Writes the value contained in register rA to the control register ctlN.
Exceptions	Supervisor-only instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `N` = Control register index of operand ctlN

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					0					0x2e
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x2e					N					0x3a					

wrprs

Instruction	write to previous register set
Operation	prs.rC ← rA
Assembler Syntax	`wrprs rC, rA`
Example	`wrprs r6, r7`
Description	Copies the value of rA in the current register set to rC in the previous register set. This instruction can set r0 to 0 in a shadow register set.
Usage	The previous register set is specified by status.PRS. By default, status.PRS indicates the register set in use before an exception, such as an external interrupt, caused a register set change. To write to an arbitrary register set, software can insert the desired register set number in `status.PRS` prior to executing `wrprs`. System software must use `wrprs` to initialize `r0` to 0 in each shadow register set before using that register set. If shadow register sets are not implemented on the Nios II core, `wrprs` is an illegal instruction.
Exceptions	Supervisor-only instruction Illegal instruction
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					0					C					0x14
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x14					0					0x3a					

xor

Instruction	bitwise logical exclusive or

Operation	rC ← rA ^ rB
Assembler Syntax	`xor rC, rA, rB`
Example	`xor r6, r7, r8`
Description	Calculates the bitwise logical exclusive-or of rA and rB and stores the result in rC.
Exceptions	None
Instruction Type	R
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `C` = Register index of operand rC

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					C					0x1e
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x1e					0					0x3a					

xorhi

Instruction	bitwise logical exclusive or immediate into high halfword
Operation	rB ← rA ^ (IMM16 : 0x0000)
Assembler Syntax	`xorhi rB, rA, IMM16`
Example	`xorhi r6, r7, 100`
Description	Calculates the bitwise logical exclusive XOR of rA and (IMM16 : 0x0000) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IMM16										0x3c					

xori

Instruction	bitwise logical exclusive or immediate
Operation	rB ← rA ^ (0x0000 : IMM16)
Assembler Syntax	`xori rB, rA, IMM16`
Example	`xori r6, r7, 100`
Description	Calculates the bitwise logical exclusive OR of rA and (0x0000 : IMM16) and stores the result in rB.
Exceptions	None
Instruction Type	I
Instruction Fields	`A` = Register index of operand rA `B` = Register index of operand rB `IMM16` = 16-bit unsigned immediate value

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
A					B					IMM16

Instruction Set Reference Revision History

Table 8-25: Document Revision History

Date	Version	Changes
April 2015	2015.04.02	Maintenance release.

Date	Version	Changes
February 2014	13.1.0	Removed references to SOPC Builder.
May 2011	11.0.0	Maintenance release.
December 2010	10.1.0	Corrected comments delimiter (#) in instruction usage.
July 2010	10.0.0	Corrected typographical error in `cmpgei` instruction type.
November 2009	9.1.0	Added shadow register sets and external interrupt controller support, including `rdprs` and `wrprs` instructions.
March 2009	9.0.0	Backwards-compatible change to the `eret` instruction B field encoding.
November 2008	8.1.0	Maintenance release.
May 2008	8.0.0	• Added MMU. • Added an Exceptions section to all instructions.
October 2007	7.2.0	Added `jmpi` instruction.
May 2007	7.1.0	• Added table of contents to Introduction section. • Added Referenced Documents section.
March 2007	7.0.0	Maintenance release.
November 2006	6.1.0	Maintenance release.
May 2006	6.0.0	Maintenance release.
October 2005	5.1.0	• Correction to the `blt` instruction. • Added U bit operation for `break` and `trap` instructions.
July 2005	5.0.1	• Added new `flushda` instruction. • Updated `flushd` instruction. • Instruction Opcode table updated with `flushda` instruction.
May 2005	5.0.0	Maintenance release.
December 2004	1.2	• `break` instruction update. • `srli` instruction correction.
September 2004	1.1	Updates for Nios II 1.01 release.
May 2004	1.0	Initial release.

Document Version	Changes

2019.08.21	• Corrected **Operation** for:
	  • cmpeqi
	  • custom
	  • ldw / ldwio
	• Corrected **Instruction Type** for:
	  • cmpge
	  • cmpgei
	• Corrected **Bit Fields** for:
	  • custom

2018.04.18	Implemented editorial enhancements.
2016.10.28	Maintenance release.
2015.04.02	Initial release
